AN UNUSUAL OUTBREAK OF TYPHOID FEVER

MAZYCK P. RAVENEL, M.D.

Professor of Bacteriology in the University of Wisconsin; Director
of the State Hygienic Laboratory

AND

K. W. SMITH

Bacteriologist State Hygienic Laboratory; Instructor in Medical
Bacteriology in the University of Wisconsin

MADISON, WIS.

Soon after the opening of the University of Wisconsin on Oct. 1, 1908, there occurred a localized outbreak of typhoid fever which presented such unusual features that we are making a record of it, hoping that it may prove useful to those interested in this disease, and especially to those having supervision of students at centers of education.

Very near the campus is an unusually well-kept and popular boarding-house, patronized not only by students, but also by a number of the younger members of the faculty. It has been running for some six years, and no trouble has occurred there before. As in many other such places, students are employed as waiters and help-
ers in the pantry.

The house opened with the beginning of the scholastic year, and soon had from ninety-five to one hundred boarders, many applicants being turned away. The working force consisted of the landlady and her two sisters, a cook, two young women who had just reached America from Norway, and thirteen student helpers, most of whom were waiters. Two or three of them assisted in scraping the used plates and in wiping and stacking the clean plates and dishes. While hot water was used, there was no attempt made at thorough sterilization of utensils.

About the middle of October about fifty or sixty of the boarders were attacked by diarrhea and nausea, some being sick for several days. The majority, however, recovered promptly without having consulted physicians. It has not been possible to determine the cause of this outbreak, but it was attributed by some to real and by others to bananas. A number who ate of both escaped, however.

During the last week of October a number of the boarders became ill, the general symptoms being headache, lassitude, loss of appetite, and pains in the limbs. The general opinion among the sufferers seems to have been that they were suffering from grip. The first case reported to the Hygienic Laboratory was on October 29, the patient having been at that time sick for one week. Others followed in rapid succession, and by November 15 more than forty cases of illness were known to exist.

The symptoms in most cases were not well defined,

but typhoid fever was suspected in several by the physician in attendance. The first Widal examinations made in the laboratory were negative. A number of the sick students went at once to their homes without having seen physicians. Many of these were heard from later, through the sending of their blood to the laboratory for examination, a positive Widal being found in the great majority of them. Some returned to their work, but continued in poor condition, and finally reported at the laboratory for examination. In a number of cases the symptoms were so mild that the men continued at their work without medical advice; some did half work, resting part of the time.

As far as possible all such cases were investigated, those of students who went home and those of students who did half work, and in all was a positive Widal reaction found. A typical case may be given.

M., the son of a physician, was one of those affected with nausea and diarrhea. He went to his home, where his father made a diagnosis of ptomain poisoning. On his return to the university he continued in poor condition, and finally reported to us on October 30. We found him cyanotic, anemic, and with a temperature of 97.5 F. His blood gave a high positive Widal.

Among those stricken were the two Norwegian girls who worked in the kitchen and pantry. In less than one month forty-one cases of typhoid fever occurred among those boarding or working at this house, three of which terminated fatally. Only one case occurred later than November 15—that of a student waiter.

During the same time there was only one case of typhoid fever among the students not boarding at this house, and only three or four other cases in the city of Madison. Madison is free from typhoid fever at all times, the water being of unusual purity.

Every possible source of infection was studied. The water used at the boarding-house was from the city supply, which is of known excellence. Bacteriologic examinations were made, however, and no pollution detected. The ice was found to be of exceptional purity on several examinations. Furthermore, its source was traced to an inland city, the inhabitants of which were free from any outbreak, though this same supply had been used continuously all summer. It had been harvested at least six months previously, and it is known that the typhoid germ seldom survives freezing for this length of time. The milk supply was investigated, but no cause for suspicion found.

The possibility of infection through raw vegetables or oysters was excluded. Only one old privy vault existed in the neighborhood, and no infection of this could be traced. The windows of the boarding-house were screened, and flies had not been troublesome.

Attention naturally turned to the detection of a typhoid-carrier among those employed in preparing and

serving the meals. The following history was elicited: E. L., a student employed to scrape, wipe, and stack plates and dishes, had resumed his duties on the opening of the house, having served in this capacity during the previous year. Immediately on his return to work he complained of having "no taste for food," which he attributed to the change of life from the country to the city. About October 20 he gave notice to the landlady that he would probably have to give up work on account of illness, and within a day or two went to Janesville, Wis., where he consulted an optician for his intense headaches, believing that his eyes were at fault. His parents urged him to remain at home until he felt better, and observed at this time that he had fever. He returned to work, however, but on October 30 gave up his place and went home, where he died two weeks later. The death of this student made it impossible to obtain a more complete history, but there can be no question that he was in the early stages of typhoid fever when he returned to Madison from vacation. We have not been able to find out at what time his bowels became loose. His duties were such that he handled utensils after they had been washed, affording an opportunity for their infection.

The exclusion of every other possible source has forced the conviction that the outbreak was caused by this method of infection. Furthermore, the outbreak ceased shortly after this student went home, only one case having occurred after such a lapse of time as to throw any question on this source of infection. In this last case the student appeared to be ill at least two weeks before he finally succumbed on November 25. He was repeatedly questioned by one of us (Dr. R.), who believed he was ill. He was an advanced student in bacteriology, had given much assistance in studying the outbreak, and was a man of more than average ability; hence his statements were given more weight than seems to have been justified. His blood gave a high and rapid positive Widal as soon as he complained of illness, indicating an infection of some standing.

The boarding-house was closed for several days on November 6 and disinfected, after which it was allowed to open again, and no case of illness has occurred since.

One fact seems to militate against the above explanation, namely, the rapidity with which the patients came down, the great majority of them giving up between November 3 and 10, the 3d, 6th, and 7th yielding a particularly large number. This may have indicated that a large number of persons were infected at the same time. Probably suggestion had something to do with this, as on these days the house was inspected, closed, and fumigated, and there was considerable excitement over the large number of students taken ill. This, however, only explains the giving up—not the infection.

Another problem which presented itself was the possibility that the choleraic outbreak in November may have been due to a massive dose of typhoid bacilli. If such was the case the origin of the germs remains a mystery. Paratyphoid appears to follow meat poisoning, but all of our cases gave typhoid agglutination—none paratyphoid—so that paratyphoid may be excluded.

In order to gain as much light on this point as possible we have traced as many of these students as we could find and examined their blood by the Widal test. Two gave a prompt agglutination, though sick only for two days, and having no previous history of typhoid fever. All others were negative.

While every clinical type of the disease was observed

in this outbreak, certain features seemed to have been predominant. The headache was in the occiput and pain extended down the back of the neck. Constipation was more frequent than diarrhea.

Before allowing any one who had been ill to return to work in any capacity in this house the urine and feces were examined. No typhoid-carrier was found among them and no case of sickness has developed since November.

THE COMBINED COURSE FOR THE DEGREES OF A.B., OR B.S., AND M.D.

JOHN MILTON DODSON, M.D.

Dean of the Medical Courses, University of Chicago
CHICAGO

Within the last decade there has developed a plan in several American universities under which a student takes, during the junior and senior years, those sciences which constitute the first two years of the medical curriculum. Credit for the successful completion of the work in these branches is permitted to count both toward a baccalaureate degree in the collegiate department and toward the degree of M.D. in the medical school. The student is thus able to secure the baccalaureate degree and the degree of M.D. in from six to seven years after his completion of the high school course and his matriculation in the university.

The plan has extended rapidly, it being now in operation in over thirty American universities. It is believed by many educators to be the best solution yet offered of the problem of how to provide a good many students with a fairly adequate premedical training and to induct them into the study and later the practice of medicine at a reasonably early age.

On the other hand, the custom is pronounced by one distinguished educator to be "pernicious," by another to be "a very dangerous process," that, indeed, "there is no more alarming process now going on in the United States in regard to education than this." Associations of college presidents have protested against it, and a resolution to prohibit the practice adopted a year ago, is now under reconsideration by the Board of Regents of the University of the State of New York.

The importance of the question warrants the fullest discussion by all who are interested in the subject. It is the purpose of this paper to inquire whether the combined course is a dangerous tendency which degrades the baccalaureate and medical degrees, or whether it is the logical, if not the inevitable, outcome of educational methods now all but universally adopted; whether it has not assisted markedly in elevating the standards of medical education in this country, and in improving the character of the instruction in the fundamental medical sciences.

HISTORY

The plan is the outgrowth of a custom which arose about twenty years ago of granting advanced standing on the medical course, both in time and subject, to the holders of a baccalaureate degree who had completed, in their collegiate course, some of the studies of the medical curriculum. At that time the requirement for admission to most of the American Medical Colleges comprised less than is covered in the first two years of a high school course, and no medical colleges exacted more than a diploma of a four-year high school. It was felt by the medical faculties who instituted the custom that, both because of his more adequate mental

training and greater power of accomplishment and because the college graduate had already completed some of the work of the medical curriculum, he might readily complete the three years medical course in two sessions, and this he was permitted to do; while, later, when the medical course was extended to four years, he was permitted to complete it in three years. It was believed that this concession would encourage young men who contemplated the study of medicine to take a college course before entering the medical school, and this effect it undoubtedly had with many students.

This custom continued in operation very generally among the medical schools until about four years ago, when the rulings of the boards of medical examiners in several states prohibited the practice. How illogical, unjust and unwise were these rulings of the examining boards will be discussed later on in this paper.

THE UNIVERSITY MEDICAL SCHOOL

Some medical schools were at that time departments of universities, and within a few years, by union or affiliation, a considerable number of independent medical schools became such. The application of the custom of granting advanced standing to the graduates of the collegiate departments of their own universities resulted in a combination and shortening of the collegiate and medical courses to six or seven years. Coincident with these developments, a radical change was taking place in the methods and personnel of those engaged in the teaching of the fundamental medical branches—chemistry, anatomy, histology, embryology, physiology, physiologic chemistry and pharmacology, bacteriology and pathology. The rapid progress and growing importance of these branches made it impossible for them to be taught adequately by physicians engaged in medical practice, and pursuing these subjects as an incidental avocation. Within a few years, in all of the better medical schools, they were transferred to men, each of whom devoted his time and energies exclusively to research and teaching in his chosen branch. And thus, with competent instructors and the introduction of laboratory methods with ample equipment, these medical sciences came to be, in the truest sense, branches of general science, in every way as well adapted for purposes of general culture and the development of the mental faculties as are other sciences in the college curriculum. Under the elective system, in vogue in most of the larger universities, the logical outcome was obvious. It can best be stated by the relation of a specific case.

An Illustrative Case.—A few years ago a medical school became affiliated with a neighboring university. The medical faculty had already decided to advance its admission requirements in the near future and to demand the completion of the first two years of the collegiate course in the university, or some other college of equal rank. The required course for the medical degree extended over four sessions of nine months each. In the university the curriculum for the freshmen and sophomore years was in part prescribed, in part elective. It included the courses in physics, chemistry and biology, and gave abundant opportunity to secure the courses in English, German or French, mathematics, history, etc., which the medical faculty deemed requisite for admission to the medical school. The last two years of the curriculum for the baccalaureate degree were elective, except that three months of work was specified in philosophy and psychology. (This provision has subsequently been changed so that the student may take these branches in the first two years if he prefers so to do.)

Moreover, the university possessed a department of anatomy, both gross and microscopic, of neurology and of physiology; embryology and bacteriology were taught in the department of zoology. Provision was about to be made for physiologic chemistry, and pharmacology, as, in a large sense, a branch of physiology could readily be provided for, as could fundamental pathology. Under the regulations of the university, in operation since its beginning, a student seeking the degree of bachelor of science could elect for the work of his junior and senior years courses in these departments, and when he had completed them he had completed all the work of the first two years of the medical curriculum prescribed in this as in virtually all other medical schools. The facilities for instruction in these fundamental medical sciences in the university were in every way superior to those in the medical school. The logical result of this situation was a transfer of the work of the first two years of the medical curriculum to the university, and at once it became possible for a student to secure the degree of B.S. in the university and of M.D. from the medical school in from six to six and one-half years. This arrangement involved no concession whatever on the part of the university, no departure from its long-established regulations concerning the baccalaureate degree. So far from any concession being made by the medical school, the change was a distinct gain in every way, the fundamental branches being taught under far better conditions and much more efficiently than ever before.

There was no logical escape from this deduction of the combined course from the conditions existing. No university with a medical department, offering instruction in the fundamental medical branches of the proper sort, can deny its students credit in the medical subjects on the course for a bachelor's degree, unless it either repudiates the elective system or declares these subjects not to be branches of general learning. Can the present day university adopt either of these alternatives?

THE ELECTIVE SYSTEM

Of the elective system it is hardly too much to say that its validity has passed beyond the realm of discussion. No other educational method in the last quarter century has made such rapid progress toward universal acceptance. It is in operation to-day in one form or another, more or less completely, in every university of any standing. It will be discussed more fully in a later portion of this paper.

And are not these medical subjects properly included in the university curriculum? Let us inquire.

MEDICAL SUBJECTS BRANCHES OF GENERAL LEARNING

Of chemistry, histology, embryology and bacteriology there can be no question, for they have been taught in many colleges and universities for years—long, indeed, before the question of their relation to the medical curriculum came under discussion. Human anatomy, with dissection, while taught until recent years only in the medical school, is surely a legitimate branch of vertebrate and comparative anatomy—the crowning topic indeed—quite as much as it is a medical subject. No department of anatomy in a university can be regarded as complete unless it offers its students opportunity for the study of the human body. The materials for its pursuit are not so readily procurable as are the bodies of the lower animals, but the experience of many universities, and even of smaller

colleges having no medical departments, has shown that they are not inaccessible under modern statutory provisions. That the application of human anatomy is chiefly to medicine, and that anatomic science originated and was for centuries studied and taught only in the medical schools, does not alter the fact that logically it is a great and important branch of zoology, and, as such, is entitled to a place in the university curriculum.

No science is of more universal interest and importance to all classes of students than physiology, though it is strange that this fact has been so slowly realized and that few subjects have been more inadequately taught. It has long been the custom in most colleges and high schools to offer instruction in physiology consisting of lectures, recitations from a text-book and occasional demonstrative experiments. Physiology can no more be properly taught than can any other science without laboratory experimentation by the individual student. Of late years universities are coming to realize this, and a chair of physiology, occupied by a competent investigator and teacher of this science, devoting his time and energies exclusively thereto, with adequate laboratory equipment and instructional force, is recognized as an essential department of a university. Such a department of physiology is the best possible place for the medical student to study this subject, and it matters little whether the department be called medical or otherwise.

PHARMACOLOGY AND FUNDAMENTAL PATHOLOGY AS GENERAL SCIENCE

There are but two other branches of any moment which are to-day usually included in the first two years of the medical curriculum, namely, pharmacology and pathology, and concerning these there may be more room for discussion—that is, as to their right to be regarded as branches of general learning and so entitled to inclusion in the university curriculum? Two points are to be noted in this connection: first, fundamentally considered both of these subjects are but phases or adjuncts of physiology; second, if this be not comprehended and conceded in any particular institution, they may be deferred to the junior year of the medical course, as is the custom in a number of the best medical schools. This latter alternative will become more feasible as the fifth year of clinical instruction, now contemplated by some of the better schools, and to consist, for most students, of service as an interne in a hospital, comes to be generally adopted.

To return to the first point, it is not difficult to demonstrate that, in the truest sense, pathology and pharmacology are fundamental sciences—essential phases of physiology. Pharmacology, which consists in the study of the effect of drugs on the animal organism, is an indispensable method of physiologic investigation, and its technic is wholly that of the physiologic laboratory. Indeed, while the medical student ordinarily would pursue the study of drug effects somewhat farther than would the student of pure physiology, no one can proceed very far in the latter branch without taking up the methods of pharmacology and he is constantly resorting to them throughout his further study of that science. To proceed further in the pursuit of what we call pharmacology is but to continue work in physiology. The pathology which is had in mind in this connection is by no means the pathologic anatomy which until recently constituted practically all that was known and taught as pathology. That was, indeed, a purely tech-

nical medical subject, related almost exclusively to the curriculum of the medical college proper. It is obvious that a knowledge of the intimate nature of disease in the animal organism could never be derived from an observation, however exhaustive and microscopic, of the end-results of pathologic processes, in a word, from the study of pathologic anatomy. Such a knowledge can only come from a study of the physical and chemical forces which produce these changes. Furthermore, such a study must be largely conducted by the method of experiment, and this, too, on organisms of such simple structure and in such environment as make it possible to know and to control all of the possible factors concerned in producing the changes observed. Such pathology is simply the physiology of the abnormal, or of the normal in an abnormal environment and as such this science is indissolubly bound up with physiology proper. Indeed, pathology has contributed largely to our knowledge of physiology, and such experimental work as that of Loeb and others in the study of simple organisms in an abnormal environment which can be varied accurately and at will, is quite as truly pathology as it is physiology. It is in this kind of pathology that the hope for future progress in that science chiefly lies, and it is with this sort of pathology that the student of medicine must begin his study of the science of disease. It is rapidly coming to make up the major part of the first course in this science as it is taught in the university medical schools. Its methods, its technic, its modes of observation, experiment and deduction differ in no material respect from those of pure physiology and physiologic chemistry, of which it is an adjunct science.

Is such a science not deserving of a place in the university curriculum? If the student of pure science, who has elected physiology as his field, is led to extend his inquiries into the field of the abnormal, shall not the university provide him with a place and facilities for such study? And is the work he does along such lines not quite as potent for the training of the faculties as that he may do in any other science in the curriculum? Is it not quite as deserving of credit in the course for a baccalaureate or for a higher degree as is accomplishment in any other university department? The right of pathology to a place in the university curriculum has been adequately set forth by Prof. E. O. Jordan in a recent address.

THE METHOD OF TEACHING THE FUNDAMENTAL MEDICAL SCIENCES

It is contended by some that the method of teaching these medical sciences to medical students must be essentially different from that by which they would be studied by persons having no intention of entering into clinical or practical medicine. In my opinion this notion is fallacious. Fortunately, in the better medical schools this idea is rapidly coming to be more a matter of theory than of practice, for with the transfer of the teaching of these sciences to the hands of men who are devoting their lives to their pursuit, the method of instruction grows constantly more broad and thorough. No sharp line can be drawn between applied and pure science, and the only effective method of approach in any branch, no matter in what direction it is to be later applied, must be through a broad, comprehensive study of its principles, facts and methods. Such a knowledge is most likely to be secured when the study is at first pursued, with little reference to its later application. The student is then less likely to be distracted into the error of neglecting those phases of the subject which he

fancies are of no importance in the vocation for which he is preparing himself and of laying stress only on those things which he believes to be important. One can not study the application of any branch of learning until he has a fairly comprehensive knowledge of the branch itself. The mistake which our normal schools have made, and which has resulted in such an unsatisfactory product, has been in endeavoring to teach young women and men "how" to teach subjects of which they know little or nothing. An exactly analogous blunder has been made by the medical colleges in attempting to teach medical chemistry, for example, to young men who know no chemistry. To this faulty method is due the fact that so few physicians can read intelligently much of the present day medical literature with its constant reference to modern chemistry and its application to medicine. It is believed that the physicians of the coming generation, who have had their chemical training on the broad, thorough lines of the college or university, will experience much less difficulty in this regard. To students thus trained in chemistry and the other sciences fundamental to medicine, all clinical pathology, medicine, surgery, obstetrics, etc., are simply applied physics, chemistry, anatomy, histology, embryology, physiology, physiologic chemistry, bacteriology, pharmacology, and fundamental pathology, and they will be studying these as "applied" sciences throughout the rest of their lives. It is perhaps a matter of less importance whether these departments of anatomy, etc., be classified as in the college of science or in the college of medicine, though, to my mind, it is a distinct advantage to have them regarded, primarily, as departments of science. The important thing is that the spirit and method of instruction shall possess that breadth of view and insistence on thoroughness and exactitude which has surely, in our past experience, been more commonly found in the college of science. One of the chief fruits of the combined course, as offered in some schools, is the fact that it has resulted in securing for these sciences recognition as branches of general learning—as being "pure" quite as much as "applied" sciences.

DOES THE PLAN DEGRADE THE BACCALAUREATE DEGREE?

With the medical sciences taught along the lines which have been indicated, does their inclusion in the curriculum leading to the baccalaureate degree tend to degrade it? For those who still hold allegiance to the old rigid, classical curriculum, undoubtedly it must seem so, but for those who accept the modern idea of what the baccalaureate degree signifies—an idea all but universally accepted—it is difficult to conceive how any objection can be entertained as to the validity of these medical sciences in such a curriculum. The question of the acceptability of credits for work in these fundamental medical sciences, if we grant their right to a place in the university curriculum, must logically be determined without any reference to their subsequent acceptance in the medical school.

WHAT DOES THE BACCALAUREATE DEGREE STAND FOR?

In former years the degree of A.B. was granted by the American colleges on the completion of a classical course, rigidly prescribed for every student. There probably never was a time when the degree meant exactly the same course of study in any two colleges, but the differences were not material. The degree of B.S. was granted for the successful completion of a course differing from the arts course in the substitution of

work in science for some of the Greek, Latin, or other branches, usually in the junior and senior years of the curriculum. In the B.L. or Ph.B. degree the substitution of some modern language for Greek was the essential modification. In most of the large universities, and in many colleges under the elective system, these degrees have ceased to have any such significance. To quote from one of our greatest educators:

The general growth of knowledge, and the rise of new literatures, arts and sciences during the past two hundred and fifty years have made it necessary to define anew liberal education and hence to enlarge the significance of the degree of bachelor of arts, the customary evidence of a liberal education.

Is this traditional degree of bachelor of arts, which, for three hundred years, at least, has had a tolerably clear meaning, to be deprived of all exact significance, so that it will be impossible to tell what one who holds the degree has studied? I reply that the degree will continue to testify to the main fact to which it now bears witness, namely, that the recipient has spent eight or ten years, somewhere between the ages of twelve and twenty-three, in liberal studies.

The worthy fruit of an academic culture is an open mind trained to careful thinking, instructed in the methods of philosophic investigation, acquainted in a general way with the accumulated thought of past generations and penetrated with humility. The choice offered to the student does not lie between liberal and professional or utilitarian studies. All studies which are open to him are liberal and disciplinary, not narrow or special. Under this system the college does not demand, it is true, one invariable set of studies of every candidate for the first degree in arts; but its requisites for the degree are none the less high and inflexible, being nothing less than four years devoted to liberal culture.

THE ELECTIVE PRINCIPLE

As to the propriety of allowing the college student to choose his studies, I quote from the same pre-eminent authority:

The next educational principle which I believe to apply to two-thirds of the entire educational course between five and twenty-five years of age, is the principle of selection or election of studies. In the first three or four years of a child's education, say from five or six to nine years, there are not so many possible subjects of equal value and necessity but that the child may pursue them all to some adequate extent; but by the ninth or tenth year of age more subjects will claim the child's attention than he will have time for and therefore arises the necessity for election of studies. As the child advances from the elementary to the secondary school and from the secondary school to the college, the number and variety of subjects from which to choose will rapidly increase until, in the department of arts and sciences in the university he will find that he cannot attempt to follow the one-twentieth part of the instruction offered him. . . . Who shall make the selection? is really the only practical question. The moment that we adopt the maxim that no subject shall be attempted at all, unless it be pursued far enough to get the training it is fit to supply, we make election or selection of studies a necessity. This principle has now been adopted by all colleges and universities worthy of the name.

A mental discipline which takes no account of differences of capacity and taste is not well directed. It follows that there must be variety in education instead of uniform prescription. To ignorant or thoughtless people it seems that the wisdom and experience of the world ought by this time to have produced a uniform course of instruction good for all boys, and made up of studies permanently pre-eminent; but there are two strong reasons for believing that this convenient result is unattainable; in the first place the uniform boy is lacking, and, in the second place, it is altogether probable that the educational value of any established study, far from being permanently fixed, is constantly changing as new knowledge accumulates and new sciences come into being.

IS THE STUDENT COMPETENT TO CHOOSE HIS STUDIES?

And who shall make the selection? Again I quote:

A well-instructed youth of eighteen can select for himself, not for any other boy or for the fictitious universal boy, a better course of study than any college faculty, or any wise man, who does not know him and his ancestors and his previous life, can possibly elect for him. I have never known a student of any capacity to select for himself a set of studies covering four years, which did not apparently possess more theoretical and practical merit for his case than the required curriculum of my college days.

When the revelation of his own peculiar taste and capacity comes to a young man, let him reverently give it welcome, thank God and take courage. Thereafter, he knows his way to happy, enthusiastic work, and, God willing, to usefulness and success.

And if the student's tastes, capacity and ultimate goal incline him to select the fundamental medical sciences as a part of his arts or science course, shall he be denied the privilege? Are these studies not calculated to make for "liberal culture?"

THE CULTURAL VALUE OF THE MEDICAL BRANCHES

I quote again from the same authority:

The training of a medical student, inadequate as it is, offers the best example we have of the methods and fruits of an education, mainly scientific. The transformation which the average student of a good medical school undergoes in three years is strong testimony to the efficiency of the training which he receives.

It speaks volumes for the force of medical practice that out of such raw material there could be produced in the course of a few years so fair a proportion of skillful, humane and successful practitioners. We have here a demonstration that medical study, contrary to the too common opinion, is, to a man of ordinary intelligence and conscientiousness, refining, developing and uplifting.

There is no line between culture subjects and professional subjects. There is absolutely no line. I read the other day an admirable definition by President Hadley of what we wanted the college to effect, not the professional school—presumably Yale College. He said we wanted to teach the college youth civic duty and religious earnestness, and health of mind and religious aspiration; he wanted to teach him public service as the root of American life and therefore of American education. Now, that is true as gospel, gentlemen. It is the educational gospel. But, in my judgment, it is not the gospel of the American college only, it is the gospel of American education from the primary school through the professional school, and I know of no subject better adapted to develop the sense of civic duty, of public service, and of moral and religious earnestness, than the subjects taught in the medical school.

Shall we not agree with these significant and emphatic expressions from one of the greatest educators of our time? And if we do so agree, can there be any possible doubt of the propriety of including the fundamental medical sciences in the university curriculum and counting credits for work therein on the course for a baccalaureate degree? So far from degrading, does not such a procedure enlarge the possibilities of the course and enhance the significance of such a degree?

HAS IT DEGRADED THE DEGREE OF M.D.?

Has the combined course operated to degrade the degree of M.D. and to lessen its significance in the United States? Up to five or six years ago no medical college in this country, with one exception, required more than a high school diploma for admission—most of them admitted students with considerably less than this. The exaction of two years of college work, the minimum demand of the combined course, was there-

fore a marked advance on previous standards. Moreover, it appears to have been the step which has brought about a general advance in admission requirements. For nearly twenty years we have had in this country a medical school whose minimum requirement is the possession of a bachelor's degree. Its high standards and distinguished service have been a source of great pride and satisfaction to the American medical profession. Such an institution was needed at the time of its foundation—but we have needed perhaps far more, a general uplift all along the line—an elevation of the character and the standards—especially of admission—of all medical schools. No material progress was made toward such an increase until the proposition to require one or two years of college work (not four) was made a few years ago. How gratifyingly rapid has been the upward movement since that time is shown by the last report of the Council on Medical Education of the American Medical Association. About sixty medical colleges have announced their intention to require at least one year of college work by the autumn of 1910; over thirty of these colleges will require two years; the state boards of medical examiners in at least two states no longer recognize the diplomas of medical students who do not take two years of premedical college work, and four others are soon to exact at least one year of such work. Emphatically, the combined course has not degraded but has distinctly elevated the degree of doctor in medicine as conferred in the United States.

WORLD-WIDE UNIFORMITY OF STANDARDS

It has been urged by some that we should seek in this country such standards as would make the degree of M.D., as conferred in the United States, uniform with that given throughout the world. It is to be said of this suggestion that it is impracticable, indeed impossible, because there is no uniformity of standard in the other parts of the world. A glance at the report of the Council on Medical Education, in which the facts in regard to this matter have been very fully and very clearly set forth will show that the degree of M.D. means one thing in Great Britain, another thing in France, yet a different thing in Italy, and still another in Germany, while in the Scandinavian countries it means a more prolonged period of systematic college work than anywhere else in the world. Of these several standards it is likely that a considerable majority of the medical profession of America would regard the medical standards and curriculum of Germany as approaching most nearly the ideal to which we in this country should seek to conform. Opinions differ somewhat as to just what, in our American school system, the German gymnasium most nearly approximates. It has been declared, by some, that the completion of the course in the German gymnasium means no more than the diploma from our better high schools. By others it is regarded as about the equivalent of a baccalaureate degree from an American college. The correct opinion probably, and that held by the majority of educators, is midway between these two estimates; it holds the gymnasium certificate to be about equivalent to the completion of the sophomore year of the better American university or college. If this be the case, the combined course of six years, leading to the degree of B.S. and M.D., with the additional year of interne service now sought and secured by a large number of medical graduates, approximates

closely indeed to the German plan. This fifth or interne year is shortly to be made, in at least one institution, a prerequisite for the degree of M.D.

ARE TWO DEGREES DESIRABLE, SUCH AS M.B. AND M.D.?

Again it has been argued that if we are to admit students to the medical school with only two years of college credit, while many others present a baccalaureate degree, then some distinction should be made between these two groups in the kind of medical degree conferred. It has been suggested, for example, that the degree of M.B. be conferred on those students not possessing an A.B., B.S. or corresponding degree, before entering the medical school, reserving the degree of M.D. for those students who were college graduates before taking up the study of medicine. This would make the degree of M.D. a secondary or higher degree corresponding to the master's degree, and, some apparently have thought it might even come to have the significance of a Ph.D. It is a serious objection to such a plan that it would involve the amendment of the medical practice acts in many states in which the possession of the degree of M.D. is made an essential prerequisite for licensure. Under this arrangement, these two medical degrees would not be at all equivalent to the corresponding degrees in vogue in Great Britain and some of her colonies. Moreover, the degree of M.D. could never come to have a significance corresponding to that of a master's degree or to the degree of Ph.D., unless the requirements were made equally rigid. Is it not far better that the college graduate who enters the university medical school should find it possible to secure one or both of these higher academic honors, the M.S. or Ph.D., and should he not be encouraged so to do by accomplishing "masterly" or "doctorate" work in one of the medical sciences? The regulations governing these higher degrees should be in no wise relaxed, and they make it impossible for any medical student to secure them by the mere perfunctory accomplishment of the regular medical curriculum. By prolonging his residence, however, one or two years, doing creditable research in one of the medical sciences and presenting the results of his investigation in an acceptable thesis, he has the opportunity to secure this higher academic distinction (with the superior training and power for which it stands), by special research in anatomy, physiology, bacteriology, or any other of the sciences fundamental to medicine.

THE DEGREES OF M.S. OR PH.D. FOR WORK IN THE MEDICAL SCIENCES

That such accomplishment is entirely practicable in connection with and by extension of the regular medical courses in the university has already been demonstrated in at least one university, where, in the last decade ten or twelve students in the medical department have secured the degree of Ph.D., and several others the master's degree. The gain to these students in power and prestige and the gain to the medical profession which they enter can hardly be overestimated. Will it not be a distinct advantage to science, as well as to medicine, when investigative work, of the right sort, in even the clinical branches of medicine, is generally recognized as worthy of credit in the course for a Ph.D. degree, and the real unity of the applied medical sciences with the pure medical sciences is thus emphasized?

THE BEST PREPARATION FOR MEDICAL STUDY

Does the two years of college premedical work demanded by the combined course afford the best pre-

paration for the study of medicine? What is the best preparation? Is there an ideal uniform preparation for all students?

These questions naturally suggest themselves in this connection, and it can not be too strongly emphasized that the four years of high school plus two years of college work comprises not by any means an ideal, but simply the very minimum of preparation with which any young man can afford to take up the study of medicine under existing conditions. The absolute essentials, including physics, chemistry, biology and German, now regarded as indispensable by most medical educators, can not be covered in less time than this. That fact was clearly demonstrated by the investigation of the committee on college preparatory work, in its report to the Council on Medical Education in 1907. The maximum amount of time which one may devote to such preparatory work is merely a question of age, and is by no means uniform for all. It seems obvious that there is no limit to the amount of education, and of knowledge which one might, with advantage, use in the study and practice of medicine. But the *time* which one may spend in such education and the acquisition of that knowledge is distinctly limited by the necessity of his getting about the ultimate business of his life at a reasonably early age. There are two strong reasons for this—one economic, the fact that he must become a bread-winner, and, one psychologic, the fact that the mental faculties, like the muscular system, begin to "set" and to lose their power of adaptability to new lines of effort at a certain age, usually in the early twenties. It is almost universally agreed that a young man ought to graduate in medicine, to have his hospital training and to be started in the practice of his profession well under the age of thirty. Says an educational authority: "If a young man takes his A.B. at twenty-two, he can hardly hope to begin the practice of his profession before the age of twenty-six. That is quite late enough."

The conviction that, under prevailing conditions, the exaction of the baccalaureate degree for admission to the four years' medical course means for many young men, deferment of entrance into practical life much beyond this period, has been all but universal among educators. To meet this difficulty, it has been proposed (1) to abbreviate the college course leading to the baccalaureate degree to three years and even to two years; or, (2) to combine the collegiate and medical school course by (a) giving advanced credit of one year in the medical school to the holder of a bachelor's degree as formerly practiced, or (b) to permit the college student to take for his senior collegiate year, the first year in the professional school, after the plan in operation at Wabash College, the University of Illinois and some other institutions; or (c) by combining, in certain universities, the academic and professional courses as has been described in this paper. Those plans which secure four full years of study between the high school or academy and the conferring of the baccalaureate degree are surely much less objectionable than the proposition to curtail the time and work demanded for that degree. All of these combination plans should be permitted, under proper supervision and restrictions. Each has its advantages, and meets best the needs of certain students. No device for curtailing the amount of his preparation should be sought by or advised for the student who can "go the whole road" within the age limit of twenty-seven or twenty-eight, but for a long

IS THE STUDENT COMPETENT TO CHOOSE HIS STUDIES?

And who shall make the selection? Again I quote:

A well-instructed youth of eighteen can select for himself, not for any other boy or for the fictitious universal boy, a better course of study than any college faculty, or any wise man, who does not know him and his ancestors and his previous life, can possibly elect for him. I have never known a student of any capacity to select for himself a set of studies covering four years, which did not apparently possess more theoretical and practical merit for his case than the required curriculum of my college days.

When the revelation of his own peculiar taste and capacity comes to a young man, let him reverently give it welcome, thank God and take courage. Thereafter, he knows his way to happy, enthusiastic work, and, God willing, to usefulness and success.

And if the student's tastes, capacity and ultimate goal incline him to select the fundamental medical sciences as a part of his arts or science course, shall he be denied the privilege? Are these studies not calculated to make for "liberal culture?"

THE CULTURAL VALUE OF THE MEDICAL BRANCHES

I quote again from the same authority:

The training of a medical student, inadequate as it is, offers the best example we have of the methods and fruits of an education, mainly scientific. The transformation which the average student of a good medical school undergoes in three years is strong testimony to the efficiency of the training which he receives.

It speaks volumes for the force of medical practice that out of such raw material there could be produced in the course of a few years so fair a proportion of skillful, humane and successful practitioners. We have here a demonstration that medical study, contrary to the too common opinion, is, to a man of ordinary intelligence and conscientiousness, refining, developing and uplifting.

There is no line between culture subjects and professional subjects. There is absolutely no line. I read the other day an admirable definition by President Hadley of what we wanted the college to effect, not the professional school—presumably Yale College. He said we wanted to teach the college youth civic duty and religious earnestness, and health of mind and religious aspiration; he wanted to teach him public service as the root of American life and therefore of American education. Now, that is true as gospel, gentlemen. It is the educational gospel. But, in my judgment, it is not the gospel of the American college only, it is the gospel of American education from the primary school through the professional school, and I know of no subject better adapted to develop the sense of civic duty, of public service, and of moral and religious earnestness, than the subjects taught in the medical school.

Shall we not agree with these significant and emphatic expressions from one of the greatest educators of our time? And if we do so agree, can there be any possible doubt of the propriety of including the fundamental medical sciences in the university curriculum and counting credits for work therein on the course for a baccalaureate degree? So far from degrading, does not such a procedure enlarge the possibilities of the course and enhance the significance of such a degree?

HAS IT DEGRADED THE DEGREE OF M.D.?

Has the combined course operated to degrade the degree of M.D. and to lessen its significance in the United States? Up to five or six years ago no medical college in this country, with one exception, required more than a high school diploma for admission—most of them admitted students with considerably less than this. The exaction of two years of college work, the minimum demand of the combined course, was there-

fore a marked advance on previous standards. Moreover, it appears to have been the step which has brought about a general advance in admission requirements. For nearly twenty years we have had in this country a medical school whose minimum requirement is the possession of a bachelor's degree. Its high standards and distinguished service have been a source of great pride and satisfaction to the American medical profession. Such an institution was needed at the time of its foundation—but we have needed perhaps far more, a general uplift all along the line—an elevation of the character and the standards—especially of admission—of all medical schools. No material progress was made toward such an increase until the proposition to require one or two years of college work (not four) was made a few years ago. How gratifyingly rapid has been the upward movement since that time is shown by the last report of the Council on Medical Education of the American Medical Association. About sixty medical colleges have announced their intention to require at least one year of college work by the autumn of 1910; over thirty of these colleges will require two years; the state boards of medical examiners in at least two states no longer recognize the diplomas of medical students who do not take two years of premedical college work, and four others are soon to exact at least one year of such work. Emphatically, the combined course has not degraded but has distinctly elevated the degree of doctor in medicine as conferred in the United States.

WORLD-WIDE UNIFORMITY OF STANDARDS

It has been urged by some that we should seek in this country such standards as would make the degree of M.D., as conferred in the United States, uniform with that given throughout the world. It is to be said of this suggestion that it is impracticable, indeed impossible, because there is no uniformity of standard in the other parts of the world. A glance at the report of the Council on Medical Education, in which the facts in regard to this matter have been very fully and very clearly set forth will show that the degree of M.D. means one thing in Great Britain, another thing in France, yet a different thing in Italy, and still another in Germany, while in the Scandinavian countries it means a more prolonged period of systematic college work than anywhere else in the world. Of these several standards it is likely that a considerable majority of the medical profession of America would regard the medical standards and curriculum of Germany as approaching most nearly the ideal to which we in this country should seek to conform. Opinions differ somewhat as to just what, in our American school system, the German gymnasium most nearly approximates. It has been declared, by some, that the completion of the course in the German gymnasium means no more than the diploma from our better high schools. By others it is regarded as about the equivalent of a baccalaureate degree from an American college. The correct opinion probably, and that held by the majority of educators, is midway between these two estimates; it holds the gymnasium certificate to be about equivalent to the completion of the sophomore year of the better American university or college. If this be the case, the combined course of six years, leading to the degree of B.S. and M.D., with the additional year of interne service now sought and secured by a large number of medical graduates, approximates

CANCER OF THE BREAST

F. S. DENNIS, M.D.

NEW YORK

In the present contribution, I shall refer only inci-
dentally to statistics. In several previously published
papers¹ I have given my statistics at length. I desire
now to express some opinions that I have formed and
facts that I have collected from a study of my own per-
sonal cases during the past twenty-five years, selecting
a few cases of cancer of the breast, and analyzing them
critically, because I believe it is a better way to arrive
at the truth, than by a promiscuous study of a large
number of cases with statistics only as a guide to de-
termine certain important facts.

I intend to consider very briefly some salient facts in
regard to the final outcome of thirty-nine cases of can-
cer of the breast, the histories of which I know from the
time of the operation to the present day. These thirty-
nine cases have been selected from a large number
solely for the reason that I have a personal knowledge
of each case from the incipency of the disease to the
present moment. All these patients have lived beyond
the three years' limit of time. One patient has lived
twenty-five years, another nineteen years, another seven-
teen years, and another fifteen years, and the rest from
three to fourteen years with no return of the disease.
In this list one was eighty-five years and another eighty-
two years old. I mention these two cases to illustrate
the fact that age itself appears to offer no barrier to an
operation for the relief of cancer of the breast.

I am convinced that a study of the cure of cancer of
the breast from a percentage point of view only has
created a very false impression among surgeons and a
depressing effect on the laity. The all-important ques-
tion for the surgeon and the patient is this: Can a
permanent cure be effected if the operation is under-
taken early, and radical in character? If this view can
be substantiated it will create hope in the patient, and
inspire courage in the surgeon.

The clinical picture of cancer of the breast has been
so drawn in past years as to create a most unfavorable
impression. The early and radical operation is certain
to efface this gloomy picture, and to draw in its place
one that will inspire hope in the unfortunate victims of
the disease. The safety of the operation is a subject
worthy of consideration. In all of the operations which
I have mentioned, and an accurate knowledge of which
I possess, there has not been a death except in two cases
of hemophilia, and such deaths are not peculiar to this
special operation, but would occur in connection with
any other major operation. The mortality therefore,
in several hundred cases would be almost nothing, even
if these cases were included, and absolutely nothing if
they were excluded. The percentage of permanent
cures, on the other hand, can not be so correctly esti-
mated because so many cases are lost sight of and there-
fore can not furnish data for statistical purposes. In
a recent small series of cases extending over three
years from the time of the operation the percentage of
permanent cures amounted to 77 per cent. In a pre-
vious series the percentage was 45 per cent., but these
operations were done earlier in the history of what is
called the complete operation. The sum total of per-
centages of cure therefore, would fall below the high
figure previously mentioned, and above the lower figure
stated in the second series. These facts certainly en-

1. Tr. Am. Surg. Assoc.

time to come a considerable proportion of earnest, capable medical students will be so circumstanced that it will not be to their best interests so to do. Experience has demonstrated that the student who has had only two years of college preparatory work, provided that has included the requisite chemistry, physics, and biology, with German and French, can pursue the medical courses alongside his fellow who has completed the college course without serious handicap. The additional two years of preparation which the latter has enjoyed is much to be desired, but its advantages are more evident in later life. A few medical schools will prefer to exclude all students who have not secured a baccalaureate degree, but the larger service to the community and to the profession is certain to be rendered by most schools if they make the entrance requirements more flexible and adjustable to the needs of a larger number of students.

IS THE COMBINED COURSE UNFAIR TO THE DETACHED COLLEGE?

It is objected by some of the colleges, having no medical departments, that the combined course is unfair to them because it tends to attract their students to the university with its medical school at the end of the sophomore year. Most of the colleges object, also, and with some reason, to the plan mentioned above, which had its origin in one of these colleges, in which a student is permitted to leave the college at the end of his junior year, taking for his senior baccalaureate course, the first year in an approved professional school—law or medicine. The contention is that these plans take the student from the college at the time when the college most desires to have him for its own.

In answer to these objections it is to be said first, that in the practical experience of at least one college, for now some years, these fears have not been realized not a single student has been tempted away by the opportunity thus offered to abbreviate his course. Second, if a few students are thus seduced from the college, there must be set off against these the hundreds of students which the increased requirements for admission to the medical school will bring to them. For a century and more the vast majority of medical students in this country have been passing direct from the common or high school, by the door of the college, into the medical school. The two years of college work now demanded by many, and almost certainly in the near future to be exacted by all medical schools, must turn this procession of students into the college, and if these hundreds of new students are thus secured to the college by the increased requirements—the direct outgrowth of the combined course—may we not reasonably feel that it is the business of the college to keep them: that it should be able to make its work so useful and attractive, and so to convince the student of the advantages of full collegiate training, as to induce him to remain until he attains his baccalaureate degree?

Two things, however, are due the college from the medical school: First, the latter should use its every effort to persuade students preparing for medicine to take the full college course if it is possible for them so to do; second, the medical school should recognize, both in time and subject credit, any and all good work done by the college in the medical branches—chemistry, histology, embryology, etc. At present it is not possible for the medical school to give such time credit. The proscription of this custom by the medical examining boards of several states constitutes one of the most

illogical, unjust, unwise and probably illegal regulations which have ever been made in connection with medical education. Illogical, because credit is thus denied for work far superior to that done in the majority of medical schools recognized by these boards; unjust, because the colleges had prepared themselves to teach these subjects in large part at the urgent solicitation of the better medical schools, only to find the promised credit in the medical schools withdrawn just as their students were prepared to ask it; unwise, because it abolished an arrangement which had been one of the most effective agencies in inducing young men to secure college training before taking up medical study. In one of the states in which this obnoxious legislation was first enacted, the board has apparently never been willing to risk its submission to the courts of law. Certainly at least eight or ten graduates in medicine, to the writer's knowledge, who had been granted a year of advanced standing for collegiate work and a baccalaureate degree by the medical school from which they graduated, have settled in this state, have applied for admission to examination for licensure, have been refused, have stated their intention to continue in practice, though ready at any time to take the regular examination, and in every instance these physicians have been subsequently requested to appear for examination, have passed the same and secured the license. Within two years, the attorney-general of this state has rendered an opinion on this obnoxious regulation flatly in opposition to the contention of the board.

Undoubtedly some colleges have attempted the teaching of medical branches which they should not have undertaken at all. Undoubtedly, the holders of a baccalaureate degree from unworthy colleges were in some instances granted advanced standing by medical schools when the medical work done was wholly undeserving of such credit. But the remedy for the abuse of a good custom lies not in the abolition of the custom, but in the correction of the abuse. What the medical examining boards should have done was to have investigated all colleges teaching medical subjects for which their students claimed advanced credit in the medical school. These colleges should then have been classified, as the boards have classified medical schools, into "recognized" and "unrecognized" or "partially recognized." This important question will never be satisfactorily or finally settled until some such plan is adopted.

SHALL THE COLLEGES TEACH MEDICAL SUBJECTS?

What shall the college teach in the fundamental medical branches? No more important question confronts the colleges to-day than this one. I have visited many scores of colleges in the past few years, and everywhere this question was among those that were uppermost in the minds of the faculties. One thing seems certain, and that is that the answer is by no means uniform for all. What subjects each college should include in its curriculum depends on many factors of locality, equipment, resources, the predilections of its teachers, the demand of its students. To settle this point there is needed the most careful deliberation of its faculty, and the advice and cooperation of those engaged in medical education. The college is much more likely to err by attempting to teach too many things than by offering too few. Many excellent colleges are unfitted to teach any medical branches at all, while others, even among the smaller schools, are doing efficient work in such subjects as histology, embryology, physiology, and human anatomy with dis-

work can be further helped by making this course coincide, when possible, with the lectures on surgery.

The subjects to be taught and the order and manner in which they shall be approached are matters on which all may differ and still attain good results. I have found the old method followed in the teaching of surgery, according to systems, very satisfactory and see no reason to change. I usually begin by considering the fundamental essential for surgery, namely, regeneration and repair in the various character of tissues; then I take up the diseases of the skeletal system, the surgical affections of the gastrointestinal system from the lips to the anus, including the gall bladder and pancreas, the thyroid gland, the genital system in male and female, including the breast, the surgical affections of the urinary system and, finally, the lymph system and miscellaneous conditions, as skin tumors, etc.

In treating all these subjects, whenever time will permit, a very hurried survey is first made of the anatomy, histology and physiology of the organ or region to be studied in order that the student may have at hand all the data necessary for the proper application of his pathologic knowledge to the study of the living patient. The pathology of the condition and the latest experimental findings are then gone into as carefully as possible with especial stress on their relationship to other organs and the region affected when such relationship exists. Methods of transference of conditions with routes, whenever traceable, are studied in detail, as in the case of metastasis of tumors, etc. Symptoms and recognized methods of treatment are touched on only when there is a pathologic lesson to be derived or when their own origin is easily and distinctly traceable to some plainly demonstrable macroscopic or microscopic pathologic condition. In other words, the student's attention is called to symptoms only when necessary to show how clearly dependent they are on abnormalities of structure, causing abnormalities in physiologic function. He is not required to know them as forming a clinical entity, but whenever possible an effort is made to make it easy for him to conjecture as to their presence from a simple process of deductive reasoning. The whole subject is then clinched by a couple of hours spent in the laboratory studying microscopic and gross specimens covering the subject considered.

This I submit as my answer to the query. "What is surgical pathology?" The subject as a distinct specialty is comparatively young, and courses in the various colleges are of very recent date. We feel that with proper encouragement both by students and co-educators much good can be accomplished for the student, his burdens made lighter instead of increased, his mental attitude toward medical subjects broadened, and at the same time there will develop a set of men trained in experimental surgery and pathology, well equipped to take up the burdens when time shall rob us of the masters of to-day.

2131 North Fifteenth Street.

Carbohydrates in Diabetes.—I. V. Lemann, in the *New Orleans Medical and Surgical Journal*, April, states that each case demands separate study, because cases differ not only in grade but in kind also. The tolerance of patients to various carbohydrates is different. Various complications call for alterations in diet, and unless the physician is prepared to give intelligent attention to these details he can not hope for good results from the diet he prescribes for his diabetic patients.

CANCER OF THE BREAST

F. S. DENNIS, M.D.

NEW YORK

In the present contribution, I shall refer only incidentally to statistics. In several previously published papers¹ I have given my statistics at length. I desire now to express some opinions that I have formed and facts that I have collected from a study of my own personal cases during the past twenty-five years, selecting a few cases of cancer of the breast, and analyzing them critically, because I believe it is a better way to arrive at the truth, than by a promiscuous study of a large number of cases with statistics only as a guide to determine certain important facts.

I intend to consider very briefly some salient facts in regard to the final outcome of thirty-nine cases of cancer of the breast, the histories of which I know from the time of the operation to the present day. These thirty-nine cases have been selected from a large number solely for the reason that I have a personal knowledge of each case from the incipency of the disease to the present moment. All these patients have lived beyond the three years' limit of time. One patient has lived twenty-five years, another nineteen years, another seventeen years, and another fifteen years, and the rest from three to fourteen years with no return of the disease. In this list one was eighty-five years and another eighty-two years old. I mention these two cases to illustrate the fact that age itself appears to offer no barrier to an operation for the relief of cancer of the breast.

I am convinced that a study of the cure of cancer of the breast from a percentage point of view only has created a very false impression among surgeons and a depressing effect on the laity. The all-important question for the surgeon and the patient is this: Can a permanent cure be effected if the operation is undertaken early, and radical in character? If this view can be substantiated it will create hope in the patient, and inspire courage in the surgeon.

The clinical picture of cancer of the breast has been so drawn in past years as to create a most unfavorable impression. The early and radical operation is certain to efface this gloomy picture, and to draw in its place one that will inspire hope in the unfortunate victims of the disease. The safety of the operation is a subject worthy of consideration. In all of the operations which I have mentioned, and an accurate knowledge of which I possess, there has not been a death except in two cases of hemophilia, and such deaths are not peculiar to this special operation, but would occur in connection with any other major operation. The mortality therefore, in several hundred cases would be almost nothing, even if these cases were included, and absolutely nothing if they were excluded. The percentage of permanent cures, on the other hand, can not be so correctly estimated because so many cases are lost sight of and therefore can not furnish data for statistical purposes. In a recent small series of cases extending over three years from the time of the operation the percentage of permanent cures amounted to 77 per cent. In a previous series the percentage was 45 per cent., but these operations were done earlier in the history of what is called the complete operation. The sum total of percentages of cure therefore, would fall below the high figure previously mentioned, and above the lower figure stated in the second series. These facts certainly en-

1. Tr. Am. Surg. Assn.

courage the surgeon to hope for even better results, and as we learn more about the disease and still further improve the technic of the present operation, the future holds out even greater encouragement for more brilliant results in the cure of a disease, which in former years baffled the skill of the greatest surgeons of the day.

PERMANENT CURE

The permanent cure of cancer of the breast is a subject in which the surgeon as well as the patient take the greatest interest. All other subjects, such as etiology, diagnosis, operation, and the like, are insignificant to the patient as compared with that of the permanent cure.

What constitutes a permanent cure? Authorities differ on this question. No one is willing to admit a less time than three years as decisive. Recently some surgeons have placed the limit of time as five years. In some of my cases ten to eighteen, and even twenty-five years have elapsed with no return of the disease.

The percentage of returns after three years is so insignificant that it would seem wise for surgeons to accept this standard, not only for the encouragement of the patient, which is no small fact in the management of the disease, but because it establishes a fixed standard from which the case from an operative as well as an optimistic point of view can be judged.

ADVISABILITY OF OPERATION IN ADVANCED CASES

There is much diversity of opinion on this question. From my own experience I feel certain that it is a wise course to operate unless the mediastinal glands are involved, or unless there is visceral metastasis, or the growth is adherent to the chest wall. I have been astonished at some results after operation, in cases in which I felt absolutely certain a return and death would follow in a few months. Yet these patients have recovered and have remained free from the disease for years, and thus have demonstrated the error of a too conservative view held by the profession at large.

In some cases in which the outlook was most unfavorable, as manifested by extensive ulceration, hemorrhage, wide-spread axillary involvement, the final results have been entirely satisfactory. No better proof of this statement can be made than by a brief reference to three cases occurring in the list of thirty-nine cases of cancer of the breast. It seems pertinent to call attention to these three cases because they demonstrate the possibility of a cure when everything looked hopeless. I admit that we can not place much reliance on a cure when cases present such a chain of unfavorable symptoms. It only shows that surgeons should not withhold an operation from the patient, even when the outlook is most discouraging. The patients should have the benefit of the doubt; it is always best, however, to explain to the friends the situation, and then they will not be too greatly disappointed if the operation is attended with a quickly fatal result.

The first patient had a foul, ulcerating, hemorrhagic, and fungous breast, with axillary enlargement. I advised the operation, not with the expectation of curing the disease, but purely from an humanitarian point of view. I felt sure that the hemorrhages could in a measure be controlled, the offensive smell to a greater or less extent be removed, the constant pain, at least for a while, be relieved, and the patient be made more comfortable during the few months she lived. To my surprise after nine years this patient has been free from

the disease, and to all intents and purposes is at the present time in perfect health. The operation was radical as the circumstances permitted, and I am at loss to explain the cure under these unfavorable conditions.

The second patient was the victim of a fungous, hemorrhagic foul-smelling carcinoma of the breast. I hesitated to operate at all, but did so at the request of the husband, with a full understanding that the operation was one to palliate the distressing symptoms, and with no expectation of cure. This operation was performed five years ago, and only recently the patient died from an acute disease, with no evidence of any return of the cancer.

Both of these tumors were examined by microscopists of world-wide reputation, who pronounced them carcinoma. I merely mention these two cases in the list of thirty-nine to illustrate the fact that sometimes recovery takes place in the most hopeless cases. Such instances appear to me to urge the surgeon to operate in the most desperate cases, with the most forlorn prognosis, unless, as previously indicated, there is involvement of the mediastinal glands, or visceral metastasis, or adhesion of the growth to the chest wall. I can offer no explanation as to the behavior of these two tumors, but they both seem worthy of record as evidence that our knowledge is still incomplete in regard to the course of certain types of cancer of the breast.

The third case is one in which I had operated nearly ten years ago and later a metastasis occurred in the lung with an extensive hemothorax. By aspiration a very large quantity of bloody fluid was withdrawn to relieve a severe dyspnea. To my utter astonishment, this patient, after the paracentesis, began immediately to improve from an almost bed-ridden condition, and for many years was in fairly good health and was in the habit of coming to my office from a distance for two or three years. From a study of these cases, bearing on the subject of permanent cures, I have been impressed with the fact that the histologic formation of the tumor influences in a marked degree the question of permanent cures. For example, I have found that the tumors which show structures departing but slightly from the normal, correspond in nearly every case with the group of cases, the clinical histories of which were favorable, because in these cases no return of the carcinoma occurred. The tumors that showed a great departure from the normal structure occurred in the cases with unfavorable clinical histories. The more typical the structure, therefore, the more favorable the prognosis; the more atypical, the more unfavorable the prognosis. In other words, epithelioma develops by asexual cell proliferation; the more embryonic the cell is, the more malignant the growth; and the nearer the cell approaches the normal, the less malignant the growth.

CONDITIONS REQUIRED FOR COMPLETE RECOVERY

The early and radical operation is of paramount importance, since the facts I have already mentioned clearly demonstrate the value of this rule. The early operation is indicated because glandular infection is not likely to be present, and the patient is in better physical health, from absence of worry and pain. This fact should impress the family physician with the responsibility of referring his patient early to a surgeon, who then must assume the responsibility of this important question. No growth in the breast, however small, should be disregarded, especially if the patient is ap-

proaching the menopause. It is by a view to prophylaxis that the mortality of death from cancer of the breast is to be still further reduced.

The more radical the operation, within reasonable limits, the better the prognosis. It seems unnecessary and a loss of time to discuss this point, since it is universally admitted that the more radical the operation, the less likely it is that the disease will return. The difficulty seems to be as to what constitutes a radical operation. Surgeons agree that all skin over the infected area should be sacrificed. The breast, with Sir Astley Cooper's ligaments, should be entirely removed, the pectoral fascia and muscles should be excised, the axillary glands, the perimammary and retromammary fat, likewise the paramammary areolar tissue should be dissected out as the minimum operation. If the cancer involves the ribs, perforates the thoracic wall, and has already infected the mediastinal glands, no operation, however radical, would be attended with any success. The same rule may also apply to that form of cancer termed *en cuirasse*, or *en plaques*, or acute miliary carcinoma. I am firmly convinced that any radical operation, more than has been described, will be of no avail. The element of time should be seriously considered, since the performance of any operation which requires the patient to be under an anesthetic for four or five hours, is attended with a risk, which if possible should be obviated. These prolonged operations are sometimes followed by ether pneumonia, acute sepsis, profound shock, suppression of urine, and many other like conditions, which jeopardize the life of the patient. In other words, we must not lose sight of some of the general principles connected with surgery, at the expense of the elaboration of an operation, the performance of which eliminates some of the best precepts and practices of our art.

In most of my cases in which no return has ever occurred, even though twenty-five years have elapsed since the operation, the patients, almost without exception, were operated on within six months from the first appearance of the disease. This point seems to me of the greatest importance in relation to the prognosis, and without question the earlier the operation the more certain it is that a permanent cure can be effected. At this point naturally the question arises as to a certainty of diagnosis within six months. I admit that it is often difficult to determine with absolute certainty that any small nodule in the breast is carcinomatous. The obstacle presented by the theory that a correct diagnosis of carcinoma within six months is a *sine qua non* for operative interference has been removed in my own mind, by a rule that all nodules or tumors in a breast in a woman at the time of or near to, or after the menopause, especially with a depressed nipple and skin dimpling, should be removed by a complete ablation of the breast. The risk run is too great if surgical interference is deferred until the diagnosis is made certain.

In several cases during the past few years I have adopted this procedure, and to my surprise the microscopic report has been returned with the diagnosis of incipient epithelioma. In such cases the patients do well as they are taken early in the course of the disease, and the nodule is small and surrounded by healthy glandular tissue. In the hands of a good surgeon with aseptic environment the risk of removing the breast is so slight that it may almost be disregarded as a factor in determining the question of an operation.

A point still further to consider is that in a large majority of cases in which a nodule or tumor is felt, it is almost certain in time to become malignant, if it has not already begun to undergo malignant degeneration. This same law of early surgical interference holds good in case of tuberculous induration, in syphilitic ulceration, in actinomycosis, or in other infective processes.

The question is more difficult when the patient is a young woman, and the growth is adenomatous. Such cases are more difficult to manage; but I am still of the opinion that all adenomata in the young should be removed, and in the case of very young girls only the nodule itself excised and examined, and if then found to be undergoing epitheliomatous changes, the entire breast should be removed by a radical operation. In the case of young girls or young women, the breast can be raised by a flap with an incision under the breast and in its fold, and turned on the thoracic wall, and the adenoma attacked from the posterior surface of the gland. After excision of the adenoma the breast can be turned down and sutured with the scar completely hid from view. I have done this and preserved the symmetry of the breast; and I have record of cases of this kind in which the breast subsequently performed its function of lactation.

In cases of chronic mastitis in a woman over forty, if pain is a constant factor, and the interstitial induration is marked, the breast should be removed to prevent the possibility of malignant degenerative changes. Within a few weeks I removed a breast for painful mastitis, and Dr. Norris reports that beginning epithelioma is present.

THE MANAGEMENT OF CASES THAT DO NOT ADMIT OPERATION

These are the cases that tax the surgeon's skill, and cause severe suffering to the patient. Nothing is more distressing to the surgeon and painful to the patient than to watch the progress of a fatal disease with the full knowledge of the condition—both waiting, utterly helpless, until the end comes, and death closes the scene.

In such cases the surgeon's duty is to mitigate the suffering, and to make the patient as comfortable as possible with a view to euthanasia. The different methods of treatment of cancer of the breast, in cases in which no operation is possible, can be discussed very briefly. The *x*-ray is one of the methods now in vogue. One writer has reported a dozen cases of cancer of the breast in which cures were effected by the *x*-ray. The absence of a microscopic examination of any of the tumors, and the fact that not a single case in the list had yet reached the three years' limit of time make these cases valueless as a basis on which to study results.

The *x*-ray is a force that should not be employed by one who is not an expert in its use, because its employment even by the best men has been followed by violent dermatitis, by ulcers that fail to heal, and that finally became the starting point of epithelioma. In a recent article by Pusey, some interesting clinical facts have been brought out in connection with the *x*-ray, which are worthy of mention. He thinks that the *x*-ray is not suitable for cases of carcinoma in which the adjacent lymph nodes are involved. It is also futile in cancer of the neck, or of the viscera. In recurrent carcinoma of the breast, alleviation of suffering for a few months has followed the *x*-ray treatment, but no cures have

more than one-fourth of all breast cancers. I have only once operated on mother and daughter. Both, I am pleased to say, are still living in good health, the daughter having been operated on in June, 1904, and the mother in July, 1906. The case of the latter was one of the most interesting I have ever seen, inasmuch as the removed specimen demonstrated cancer and a number of very small abscesses—which I think were tuberculous—and Professor McFarland, the pathologist, was unable to say which was the primary condition. A photograph of the specimen is shown in my book.¹ I have frequently operated on women who gave a history of cancer of the breast in their mothers and sisters, and occasionally it has shown itself in three generations—grandmother, mother and daughter.

Before leaving the subject of diagnosis, it must be candidly admitted that in about 10 per cent. of patients cancer of the breast can not be recognized clinically in its early or operable stage, for in addition to the difficulty of differentiating between solid growths, it is even more difficult to distinguish between benign and malignant cysts. This can safely be determined only by the microscope, and that it is necessary to be most careful in separating the one from the other no experienced surgeon will deny.

It is true that a bloody or sanguinolent discharge indicates malignancy, but a clear fluid does not by any means demonstrate benignity. Nothing save the microscope can positively discriminate between simple and malignant cysts. Hence, the danger of any other treatment than excision, not only of the entire cyst wall, but of enough adjacent tissue reasonably to insure eradication of the disease. I would emphasize the fact that cysts are often malignant when they would seem macroscopically, on account of their thin walls and clear contents, to be innocent; furthermore, that the degree of their malignancy is very great, so much so that a mistake made at the time of operation may not, probably will not, be atoned for by a second and more complete operation after the microscopist has made his report. In the first place, a radical second operation, even if performed within a fortnight, is likely to result in failure on account of the liberation and distribution of epithelial cells at the time of the first operation. Secondly, the patient will generally refuse a second operation; and it is most embarrassing to the surgeon to be placed in such a position. Here, as elsewhere, partial removal may do more harm than good, stimulating the remaining cells to an unwonted growth. Therefore, there is but one reasonably safe and certain method to follow in doubtful cases: the patient's consent to a complete operation should first be obtained, explaining fully that it will not be resorted to unless the microscopic examination made at the time of the operation demonstrates its necessity. The most suspicious part of the growth should be removed, along with adjacent structures if possible, and given to a microscopist who is present and who is, moreover, familiar with making reports from frozen sections. The wound should be instantly plugged with gauze, then cauterized with the actual cautery. In this way *only* will the danger of possible dissemination of cancer be minimized. I have followed this plan more than fifteen years and have known but one malignant tumor mistaken by the pathologist for a benign one. In this case the mistake was more than pardonable, although a clinical diagnosis of cancer had been made, as it was not until many sections had been cut at the second or confirmatory

examination ten days after the first operation that carcinomatous tissue was encountered. In other words, the portion of the growth first examined was benign. That at the second examination was also found to be benign, until the thirteenth section was made and examined. Figures 1 and 2, from photomicrographs of the only lobule involved, indicate the malignant change to be in its incipency. The pathologist, Dr. Wieder, thinks it as early, and therefore as favorable a case as he has ever examined. I am indebted to him for these excellent photomicrographs. The patient was advised to have and fortunately accepted the second operation.

Admitting that mistakes must occasionally occur in the hands of those doing frozen section work, it is no more than we must expect even in the less rapid and presumably more careful work ordinarily done in the pathologic laboratory; for I have known some of the very best pathologists to make mistakes and reverse themselves after several examinations of the same tumor. Only a few weeks ago I removed what I supposed to be a large sarcoma of the breast. Figure 3 shows this specimen. In ten days after the operation the report came back from the laboratory "sarcoma undoubtedly," four or five of the best pathologists in Philadelphia having examined the specimen. In fact, it was shown at the Pathological Society of Philadelphia. Several weeks afterward a second report was sent me to the effect that the tumor was also in places carcinomatous. This opinion has been expressed by pathologists of very highest standing, among the number Professor Smith of the University of Pennsylvania, and Dr. Repplier of the Presbyterian Hospital. It is only reasonable to suppose that such apparently contradictory reports must now and then result, notwithstanding every precaution to insure accuracy primarily. This is the only case I have ever encountered in which there were both sarcoma and carcinoma undoubtedly present in the same specimen. Others have reported such cases, and it explains many strange and inconsistent things in the subsequent history of cases. For instance, it explains why the secondary or daughter growth did not resemble the parent neoplasm.

COMPLICATIONS

Next to the variety of the growth, the prognosis is most influenced by the presence or absence of enlarged glands in the axilla and elsewhere. This fact has been emphasized by every writer from time immemorial. It has been made more definitely clear by the recent statistics of the Johns Hopkins Hospital² and the Massachusetts General Hospital,³ in both of which series the cases were carefully scrutinized with reference to the involvement of the axilla. In 64 of 232 patients operated on in the Johns Hopkins Hospital, in whom there were undemonstrated glandular involvement, 51 or 80 per cent. were free from recurrence at the expiration of three years. Of 110 patients with demonstrated axillary involvement, only 24.5 per cent. were free from recurrence at the expiration of three years. Of 236 patients with palpable axillary involvement, before operation, operated on in the Massachusetts General Hospital during the decennium from 1894 to 1904, only 12 per cent. were cured by operation. Of 117 patients operated on in the same hospital, in whom no glands were felt in the axilla, 29 per cent. were cured. In nearly all of the cases, even though palpable enlarge-

3. Greenough, Simmons and Barney: *Tr. Am. Surg. Assn.*, 1907, xxv, 90.

ment of the glands was not manifest, there was found to be microscopic involvement. It is only fair to suppose that limited involvement of the axillary glands may be successfully met by operation, for in such cases the epithelial cells are confined to the interior of the glands and therefore can be entirely removed. But if there is gross involvement of the axilla, particularly if the glands have become matted and fused together, the presumption is that the capsule and tissues around the glands have also become infected and that the prognosis even after an extensive operation, must necessarily be bad. The advantage resulting from early operation, before there is palpable involvement of the axilla, and the hazard of delay until axillary involvement has taken place, could not be more forcibly shown than has been done by the statistics of two such large and representative hospitals. Moreover, the experience in these hospitals, and in all others so far as my knowledge goes, demonstrates forcibly that in cases in which axillary involvement is so great as to make

notably the skin and pectoral wall. Every surgeon has recognized the gravity of adhesion to the chest wall and the comparative futility of operation to give more than temporary relief. The statistics of the Massachusetts General Hospital, while clearly indicating this to be a serious complication, show that of 45 such patients, 5, or 11 per cent. passed the three-year limit without recurrence. Of 194 cases in which there was no adhesion to the chest wall, 41, or 21 per cent., were successful. Where the skin alone is adherent, the prognosis, while less favorable than in cases without adhesion, is better than it is where adhesion to the chest wall is present. Of 262 patients with adherent skin, only 42, or 16 per cent. were cured by operation. In 71 patients in whom the skin was not adherent, 23, or 37 per cent., were cured. Therefore, this complication is of much greater importance than it would at first seem, and its unfavorableness is easily appreciated by remembering the fact that the largest and most important of the lymph-bearing channels are found in the skin.

Fig. 1.—Specimen from malignant tumor, at first mistaken for benign growth; low-power view of only lobule involved

Fig. 2.—High power view of same acinus shown in Figure 1

resection of the axillary vein necessary in order seemingly to get beyond the encroachments of the disease, operation, though possibly prolonging life, has not resulted in a single cure. I would again insist on the fact that no one, however skilled, can always or usually recognize before operation the presence of enlarged axillary glands; and that such enlargement, though not detected beforehand, will nearly always be encountered when the axilla is carefully explored. It is certainly never safe to assume that enlarged axillary glands do not exist. In all cases, even cases of adenocarcinoma in which glandular involvement is less apt to occur than in other varieties, a thorough dissection of the axilla is just as important as removal of the breast itself. Only once have I operated for either medullary or scirrhus carcinoma without encountering unmistakable enlargement of the axillary nodes when the axilla was explored. Frequently I have failed to detect such enlargement before operation.

Next and hardly secondary in importance to involvement of the neighboring lymphatic glands is the adhesion of the growth to neighboring structures,

ENLARGED SUPRACLAVICULAR GLANDS

Palpable enlarged glands above the clavicle have always been considered by surgeons to be the gravest of complications, and practically to preclude operative relief. In fact, they have almost universally been looked on as a positive barrier to operation. While of the greatest significance, it must be remembered that such enlargement may be inflammatory. Of 40 patients with palpable neck involvement operated on in the Massachusetts General Hospital,² 2 were found to be free from carcinomatous involvement and were well three years after operation. All of the remaining 38 cases were fatal. Of 40 operative cases in the Johns Hopkins Hospital³ with positive involvement of the neck and the axilla, 3, or 7.5 per cent. were cured. This is perhaps the best showing that can be made in this class of cases, inasmuch as the neck operation was first advised and has been insistently carried out at the Hopkins Hospital during the past fifteen years. While I have never known a patient of my own with either palpable or microscopic involvement of the supraclavicular glands to be cured by operation, I did have one

Fig. 6.—Primary skin incision.

cent. passing the three-year limit. This was the best showing, so far as I know, made by any surgeon up to that date.

These results, together with the pronouncement of Meyer and Halsted, in favor of a freer and more anatomic operation, stimulated others to greater endeavor, and, we may say, presaged the greatest advance yet made in breast surgery. At the present time it is not claiming too much to say that at least one-third of the mammary cancers which come to operation should be cured, and that early cases should give a much better prognosis — one-half or two-thirds of the patients making permanent recoveries. If the patient fortunately presents herself for operation before there is either adhesion of the skin, axillary involvement or other complication — in other words, while the disease is strictly local—80 per cent., or four out of five, should be cured.

But, taking cases as they come, early and late, we find that of 210 patients operated on in the Johns Hopkins Hospital, whose cases were traced later, 42.3 per cent. were apparently cured three years

or longer.² This is the best showing made by any hospital of which I have knowledge, but no better than a number of individual surgeons have done. It is my own belief that we shall more accurately measure the true value of any operation for cancer by taking the smaller series of surgeons who are able to follow their private patients for many years after operation. It is simply impossible to trace accurately a large number of hospital cases. I have long since been made to realize the impossibility of satisfactorily doing so and, therefore, have abandoned the attempt. In the first place, one's private patients are more intelligent, seek

advice earlier, submit to operation more readily, and if told that their safety depends on regular visits to the surgeon for at least five years after operation, they will willingly do so.

I have not for many years hesitated to tell patients that they have cancer, and, in my judgment, it is a great mistake not to do so. If the advantages of an early operation and the hazards of delay are fairly placed before patients, they will rarely hesitate. Therefore, it is

Fig. 7.—Division of pectoralis major near its insertion.

much better and fairer to them to call the disease by a name which all understand and dread rather than to call it a "tumor" or a "malignant growth," the nature of which they do not apprehend. Of course, half-truths are told with the very best and most humane motives, but the whole truth very soon dawns on the unfortunate victims with appalling force, and, mayhap, when it is too late. The truth should be told delicately and with consideration, of course, but it should be told, nevertheless.

During the ten years from Sept. 1, 1898, to September, 1908, or since my removal to Philadelphia, I have certainly operated on more than a hundred patients with cancer of the breast. Of the ward patients treated in the five hospitals with which I have been connected—I estimate them at fifty or upward—very little is definitely known. Therefore, all are excluded. Of 25 private patients operated on, which includes every patient treated from 1898 to 1905, 7 are dead and 1 is living with recurrence. This patient had, at the time of operation, a very large goiter, rapid-

Fig 8—Division of pectoralis minor at its insertion

ly increasing in size, which she declined to have removed. Dr. Fell, of Wilkes-Barre, writes me that the goiter has further increased in volume and that the opposite breast is certainly involved to a pronounced extent. Seventeen, or 68 per cent., are living in good health without local or general evidence of recurrence.

To show that my cases were at least of average severity, two of the patients had been operated on by other

surgeons and had suffered recurrences. In one of them I was compelled to resect the axillary vein to the extent of four inches on account of extensive axillary infection. Both of these are dead. In one other case the growth was so advanced that I should very likely have declined to interfere, but for the insistence of the patient's husband, who was a physician. Both he and she declined operation when I first advised it a year before, as they were about starting to California for the winter on account of his health. Two of the 17 recovered patients had adenocarcinoma, 2 had cancerous cysts, 2 medullary, and 11 scirrhous growths. One of the cured patients had both breasts affected.

Fig 9—Axilla freely exposed and vessels divided at their origin

FIG. 10.—Axillary dissection completed. Fascia, fat and enlarged glands en masse shown at base of axilla. External respiratory, or nerve of Bell, shown on the inner wall of the axilla. Subscapular nerve on the posterior wall. Sheath covering all muscles removed.

An interesting and encouraging feature of the series is that two of the cured patients were operated on during pregnancy. Both went to term. Patient 14, whose case was fatal, also had pulmonary tuberculosis. Cancer and tuberculosis rarely coexist, this being the only time I have encountered it. This was a patient of Dr. P. S. Donnellan, now residing in San Diego, Cal.

The patients whose cases are of longest standing were operated on January, 1899, May, 1900, December, 1900, and November, 1902, respectively. All are perfectly well. Figure 4 is from a photograph of the last, on whom a double amputation was done. Skin grafting was done on the right, but not on the left side.

I may add that one patient, a woman, aged 77, with a very bad heart, died suddenly within a week after the operation. As this case has no possible bearing on the subject of ultimate result, it is only mentioned for the reason that I wish to in-

clude every private case submitted for operation. Had the patient survived the operation, the chances of a radical cure would have been good, as the growth proved to be adenocarcinoma.

Since 1905 I have operated on a larger number of private cases than in the preceding seven years, and many of the patients have gone long enough to convince me that the end-results will be at least as good if not better than in the series herein reported.

My method of operating has meantime changed somewhat, all the while tending to become more radical. Two years ago I definitely abandoned all flap operations as being at least potentially dangerous. They are alluring and seductive, inas-

much as they often facilitate the closure of a wound otherwise difficult; but that they may do so to the prejudice of an abiding result there can not be the slightest doubt. He who always begins and ends his incision in the same manner for a disease so protean in its manifestations and so widely variant in its local ex-

FIG. 11.—Second skin incision. Observe the extensive undermining anteriorly.

pressions will in time necessarily be disappointed and chastened, if not disheartened utterly. If anything has been demonstrated, it is that recurrences generally manifest themselves in the skin, and that its wide removal is the prime consideration, even though the necessarily large wound made must be closed by either undermining or skin grafting.

The operative mortality was less than 1 per cent. in 2,133 operations performed by 25 American surgeons who do a very extensive operation. The radical procedure is just as safe as incomplete operations — I believe safer, because it permits accurate work in the axilla. Much of the previous heavy mortality from breast operations resulted from hemorrhage, shock and sepsis, due to wounding the vessels, especially the axillary vein, on account of an attempt to clear out the axilla through an inadequate wound.

Fig. 12—Undermining inferiorly. Muscles, breast and axillary mass being reflected prior to removal.

TREATMENT

There is but one treatment for cancer of the breast—operation—and the earlier and more radical the procedure the better.

The chances of a cure in any given case depend almost wholly on the timeliness and manner of operating. It should be unnecessary to point out the futility and harmfulness of local applications, caustics, radium and x-rays. All are time-consuming, none of demonstrated value; consequently they should not be used until after operation has failed, or possibly as an adjuvant to it in well-selected cases. Hence, it is necessary only to consider a few of the more prominent and basic principles in the operation for breast cancer. A large wound, removal of the pectoral muscles, a thorough axillary dissection *en masse*, are theoretically admitted to be necessary by practically all advanced surgeons. A few who do not remove

Fig. 13—Appearance of the wound after removal of the breast, muscles and axillary mass. A small part of the origin of pectoral muscles left as a covering for the ribs. This very much facilitates grafting, when necessary, which is rarely the case. In fourteen operations during the winter it has been necessary in only two cases.

Fig. 14.—Wound being sutured. Middle third of horizontal incision may be, if necessary, covered by skin-grafting. It is rarely necessary. Latterly the drainage tube at either end of horizontal wound is omitted.

reality is most obnoxious, and that to overcome infection traveling from breast to liver the sheath over the upper part of the rectus should be removed. I was so impressed with his views set forth at Oxford before the British Medical Association in 1904, where we appeared jointly in the discussion of cancer of the breast, that I at once began enlarging my wound internally, making a freer dissection of the epigastric triangle and removing the sheath of the rectus in all cases when the tumor involves the sternal hemisphere, especially its lower quadrant. I have always believed and frequently insisted on it previously that growths involving the inner half of the breast are deadlier than are those of the outer

the muscles cut across and retract the ends, so as to uncover the axilla, subsequently suturing them. A smaller number, I think, practice removal of the fasciæ covering the subscapular, serratus, latissimus and other muscles exposed in the axillary dissection; and still fewer continue the incision far enough internally and inferiorly to expose the sheath of the rectus in the epigastric triangle. Almost none remove it. The investigations and teachings of Mr. Handley,¹⁰ of London, indicate that carcinoma spreads peripherally by permeation of its epithelial cells along the deep fascial planes; hence the reasonableness of removing fasciæ possibly infected. Mr. Handley also insists—and he has much to support his contention—that abdominal metastases are more frequent than thoracic ones and, instead of the lungs being most often the site of secondary foci, as we formerly believed, the liver in

hemisphere. The latter metastasize to the axilla, where it is possible for us to pursue and destroy the enemy; but the former metastasize to the liver, mediastinum, lungs, sternum, ribs or vertebræ—all veritable Gibraltar—defying surgical attack by either assault or siege.

10. Cancer of the breast and its Operative Treatment, John Murray, London, 1906.

A vast majority of surgeons so plan their incisions as to work from sternum to axilla, in spite of the inherent dangers incident to such practice, first accentuated, I believe, by A. G. Gerster so long ago as 1885.¹¹

In a paper remarkable for its foresight, he used the following words: "The operation should be begun, if possible, with the evacuation of the axillary space and its contents, together with the breast and the intervening tissues, should be removed in one piece." Dr. Gerster informs me that he not only advised, but practiced, this method of operating since 1885, always clearing the axilla, and, so far as he could, ligating the vessels at their origin. He, of course, admits that the later suggestion of Halsted and Meyer (removal of the muscles) greatly facilitates both the axillary dissection and ligation of those vessels high up in the axilla, and was prompt to accept it as necessary for a complete operation.

The advantages of first attacking the axilla are direct and manifest and should be more generally appreciated. They are: First, the axilla may be so hopelessly involved as to make an attempt at removal worse than fruitless. Hence, the sooner it is known the better. Second, the blood vessels can be reached and tied at their origin, which materially lessens both hemorrhage and shock, as the same vessel is not repeatedly cut as is necessarily done in working toward instead of from the axilla. Third, the axillary space is dissected from above downward instead of from below upward, because it is both easier from a surgical and better from a pathologic viewpoint, inasmuch as the dissection is begun beyond the encroachments of the disease. Fourth, we avoid largely, if not wholly, the great danger of expressing and distributing cancer cells to adjacent tissues and remote organs as a result of manipulating the infected mamma and lymph nodes. This is a considerable, not a chimerical danger—so much so that unnecessary handling of the infected tissues should be avoided. Gerster made this clear in his paper,¹¹ and insisted that it was the chiefest danger to be feared. Fifth, a dissection *en masse* is sometimes made impossible if the work is begun at the sternum, as the heavy mass may pull on and break the axillary tail. It certainly will, if not held by an assistant, during all of which time the infected breast is being manipulated. Sixth, the functional use of the arm will be better, for the reason that in beginning at the axilla instead of ending the incision at this point greater precision is assured. The incision should not extend onto the arm, as the resulting cicatrix in such cases not infrequently restricts the limb in its future movements. This I consider of the greatest importance, as I have more than once seen after the employment of incisions which did either begin or end on the arm a cicatrix which restricted the limb in its upward and backward movements. I have not had the slightest interference with the movements of the arm since confining my incision to the chest. The axilla is reached by a straight incision extending from beneath the clavicle to an inch or less below the tendon of the pectoralis major and at least two finger-breadths internal to the sulcus between arm and chest. This permits perfect access to and work in the axilla.

The several steps of the operation as I now practice it are better shown in Figures 6 to 16 than by a description. Figure 14 shows a drainage-tube at either end of the horizontal incision. I formerly thought this necessary. Latterly I omit drainage.

CECOSTOMY AND CONTINUOUS COLOCLYSIS IN GENERAL PERITONITIS AND OTHER CONDITIONS

CHARLES A. L. REED, M.D.

CINCINNATI

A method of treatment that I have been using, for some time, in certain cases of general peritonitis and in some other conditions, is as follows:

1. Recognizing that general peritonitis is always the result of infection, I place the patient in the Trendelenburg position and operate in the usual way to find, and, if possible, to remove the source of infection.

2. Whatever may be the details of that operation, I bring up the cecum and fix it in an incision made directly over its situs, open the loop thus anchored, and in the opening I insert a soft rubber catheter which I fix by a suture to the abdominal wall.

3. I then put a self-retaining effluent tube into the rectum.

4. Through the cecal tube I subject the colon to such treatment and usage as the then existing and subsequently changing conditions may require.

Under this last heading comes, first and foremost, the treatment of patients of general peritonitis, operated on *in extremis*, that is, with a subnormal temperature, uncountable pulse and extreme distention. The first thing accomplished by opening the cecum under such circumstances is, of course, to lessen the distention of the intestines and thus make it possible to deal more effectively with the field of operation. Then immediately after the operation, or, for that matter, before it is completed, I begin continuous irrigation of the colon with normal salt solution at 110 F. About three quarts of solution are retained before the effluent current is established through the rectal tube. By this internal application of heat in direct contact with the solar plexus and by the incidental absorption of water from the colon, a reaction is generally secured with a promptness that seems phenomenal. As soon as this is secured, the free flow from the irrigator is abandoned and the drop-by-drop clysis is substituted and continued for the next twenty-four hours or longer. If the stomach is rebellious, the cecal tube is utilized for feeding the patient. The cecal tube may be retained indefinitely without interfering with convalescence.

This line of treatment is eligible not only in general peritonitis, but in several other conditions. It can be readily adopted as an elective measure, in acute gastric ulcer in which no operation has been done, but in which it is necessary to keep the stomach at rest for a considerable time. It is a capital expedient for feeding purposes following gastroenterostomy and in cases of malignant disease of the stomach or of the upper segment of the intestinal tract, in which operation is not practicable. I have already reported on its utility in certain cases of intractable disease requiring direct medication of the mucosa of the colon.

As a practical expedient this line of treatment has some obvious advantages. In the first place, it is simple and safe. In the next place, its restorative value to the patient—the application of heat, the absorption of fluid and the administration of nutritive and medicinal agents—is beyond question. The complete control thus gained over the colon facilitates the elimination of any toxins that may be lodged in that viscus. Dr. Thomas, pathologist to the Cincinnati Hospital, has made some inter-

11. New York Med. Jour., Feb. 28, 1885.

esting demonstrations in the cadaver showing that the cecal tube may be utilized for flushing the intestinal tract above the ileocecal valve. Properly predigested food introduced directly into the colon is absorbed much more readily, much more certainly and in much larger quantities than when given by the rectum, and the same fact is true of water, even by the drop method.

I wish in conclusion to urge that cecostomy rather than appendicostomy should always be adopted as the operation of choice. As compared with the presenting part of the cecum, the ceco-appendiceal juncture is an inch or more further away from the abdominal wall. The mesocecum is, furthermore, ordinarily so short and is always so inelastic that the appendix can not be drawn and held forward without a degree of tension that is fatal to its integrity. The distensive pressure of any tube inserted and retained in the narrow lumen of the appendix is another influence that causes it always to perish during the first few days after the operation. Thus an appendicostomy always, sooner or later, resolves itself into a cecostomy. It is better, however, to do a cecostomy as an elective operation

The Groton.

THE RELATION OF FOREIGN BODIES IN THE GALL BLADDER TO GALLSTONE DISEASE

JOSEPH RILUS EASTMAN, M.D.

INDIANAPOLIS

Foreign bodies of various kinds have been found occasionally in the gall bladder in association with gallstones. It is probable that the presence of a foreign body in the gall bladder may, under certain conditions, be concerned in the etiology of the stones. The question of whether any foreign body can produce gallstones quite unaided by micro-organisms has been rather conclusively answered in the negative. It is certain that smooth foreign objects may occupy the gall bladder for a long period without retention of precipitated bile salts.

Jaques Meyer introduced small ivory balls into the gall bladders of test animals and found no stones after a year.

Mignot¹ also found that certain foreign bodies, if aseptic, may be retained in the gall bladder for a long time without causing inflammation or precipitation of solids from the bile. Mignot, in his investigations found, also, that foreign bodies impregnated with virulent micro-organisms, singularly enough, did not lead to the formation of gallstones. Such virulently infected foreign bodies produced more or less violent cholecystitis and precipitation of solids but so long as the bacteria retained their virulence they could not, even with the help of the foreign body, form calculi. There resulted a sediment mixed with pus, but the sediment had no tendency to adhere to the foreign bodies. To form stones, he says, the bacteria must be attenuated. Such attenuated bacteria used in his experiments caused precipitation of the bile solids on cotton wool quite promptly, that is, within five or six months.

The above observations concerning the necessity of attenuation proved true of the *Bacillus typhosus*, *Bacillus coli*, staphylococcus, streptococcus and even the non-pathogenic *Bacillus subtilis*. Reports² of similar experi-

ments show that if attenuated bacteria and foreign bodies be introduced together into the gall bladder, stones will be formed.

In the absence of direct proof it seems reasonable to presume that much must depend on the character of the foreign body. The smooth ivory balls of Meyer doubtless produced little irritation; whereas a jagged body, if large, must produce decided irritation and if such irritation be alone unable to produce obstructive inflammation of the gall bladder or ducts it is nevertheless easily seen that the essential bacteria may readily be attracted to such a focus for, as Gilbert has demonstrated, bacteria are frequently sent out from the liver with the bile.

The Mayos³ called attention to the circumstance that the *Bacillus prodigiosus* placed in the anus appeared after two hours in the mouth and that reverse mucous currents in the intestines and ducts will similarly carry up particles of indigo carmine.

It seems not unfair to assume that bacteria may readily pass up the gall ducts from the intestines.

It is well known that entozoa are frequently found associated with gallstones. Such entozoa in their entrance into the gall bladder doubtless furnish at once the foreign bodies and the atria for infection. This is, perhaps true also of the globules of metallic mercury which have been found in gallstones.

That intestinal parasites may find their way into the gall bladder and carry with them the necessary infection is abundantly shown by many reported cases: Lobstein⁴ found round worms associated with gallstones; Gautrelet⁵ found bilharzia or intestinal flukes in connection with biliary calculi; Carless⁶ found pieces of hydatid membrane in the gall bladder and Buisson⁷ found the *Distoma hepaticum* in the gall bladder in a case of cholelithiasis. Homans found gallstone incrustations on sutures introduced through the gall bladder wall at a previous operation, here the suture presumably established an atrium. Nauche reported a case in which he found a steel needle forming the nucleus of a gallstone (Mayo Robson).

I have recently observed a similar case in which the incrustations on the needle were slight and easily removed with gauze and the gall bladder was filled with small stones.

In my case adhesions were present between the gall bladder fundus and the pylorus. It seems most likely that the needle passed directly from the pylorus into the gall bladder carrying bacteria with it. This seems also the most rational explanation of the presence of a fruit-seed in the gall bladder in the case reported by Frerichs. If, however, the ova intestinal worms may travel up the ducts with the aid of reversed mucous currents, the seed may have had a similar experience. Doubtless there are other cases in which pointed foreign bodies, owing to the presence of adhesions between the gall bladder and pylorus may be assumed to have passed directly from the latter to the former. Clarus, quoted by Poulet, in his work on foreign bodies, reports a case observed in St. George's Hospital, Leipsic, in which a needle was found very near to the gall bladder in the groove between the left and right lobes of the liver. To say that this needle passed out at the pylorus is perhaps not justifiable in view of the amazing journeys which needles have been known to make in the body.

2. Riforma med., 1901: quoted by Moynihan: Gallstones and Their Surgical Treatment, p. 45.

The following is a brief report of a case occurring in my practice:

Patient.—Mrs. H. of Walton, Ind., a patient of Dr. Carpenter, was operated on for gallstone disease on March 19. The symptoms which had led the family physician to the diagnosis of gallstones were those which are observed usually in such cases. There had been present gallstone colic, left-sided pains (suggestive of adhesions between the pylorus and the gall bladder) and shoulder pains, followed by nausea and vomiting. There were jaundice and digestive disturbances, muscular rigidity and bile pigment present in the urine as shown by Baudouin's test, also by Loeffler's blue.

Operation.—When the abdomen was opened the gall bladder was found enlarged and adherent and drawn toward the median line of the body lying in immediate relationship with the pylorus. The gall bladder was opened in the usual way. Gallstones were found, and during the removal of these the scoop caught on a mass of what seemed at first to be a very stiff string of organized fibrin occupying the lumen of the organ. On removing this with artery forceps it was seen that the tough fibrin containing bile solids surrounded a stiff, pointed object which later was found to be an ordinary short sewing-needle.

How the needle came into the gall bladder is not known. It is presumed that the woman swallowed it, but this, of course, is only a hypothesis. The woman was accustomed to use needles like that found in her work and had occasionally put such objects into her mouth, as most women do, but does not remember having swallowed a needle. If the needle was swallowed it might easily have found its way into the gall bladder in the manner suggested above.

The body of the gall bladder is, as is well known, in relation by its under surface with the first portion of the duodenum, occasionally with the pyloric end of the stomach and the hepatic flexure of the colon. The needle might have traversed the wall of the intestinal canal proper in any one of these three portions and found the wall of the gall bladder in immediate apposition with the canal, which it had just left. It does not seem at all likely that the needle backed up stream, so to speak through the ampulla of Vater, the common and the cystic ducts. To any one familiar with the causation of gallstones, the probable relationship of the presence of the needle to the stones will be clear. It is quite fair to assume that such a foreign body as the needle, having carried in infection, could provoke sufficient inflammation of the gall bladder and ducts with consequent obstruction as to lead to precipitation of the bile salts and gallstone disease. There were no stones in the ducts and the symptoms, as might be expected, have quite disappeared.

331 North Delaware Street.

The Lachrymal Glands at Various Ages.—A. Goz (Inaug. Diss., Tübingen, 1908), has made an exhaustive study of the human lachrymal glands in male and female of various ages. The tissues were fixed in concentrated sublimate or in formalin; paraffin sections stained in iron hematoxylin and Delafield's hematoxylin and benzopurpurin B. Age bears a direct relation to the size and structure of the glands. The largest were found in women of about middle age. The size of the glandular epithelium decreases after the first year, producing a widening of the glandular lumen. In advanced age there is an increase of connective tissue and an invasion of the glandular substance. It is not uncommon to find in the aged the glandular tissue thus split up into a number of islets but normally glandular degeneration from this source does not occur. The lachrymal glands of the female have a larger average size and weight than those of the male.

REMOVAL OF AN EMBOLUS FROM THE COMMON ILIAC ARTERY, WITH RE-ESTABLISHMENT OF CIRCULATION IN THE FEMORAL

JOHN B. MURPHY, M.D.

CHICAGO

Patient.—Mrs. H. S., aged 41, was admitted to Mercy Hospital at 1:40 p. m., April 29, 1909.

Family History.—Father alive, well, aged 77; mother died at 42 of pulmonary tuberculosis.

Personal History.—The patient was born in Germany and came to Chicago twenty-five years ago; married at the age of 26; habits good; used no alcoholic liquors. Menstruation began at 14 and was until one year previous of the regular twenty-eight-day type; lasted four days; quantity moderate. In the last year the patient had had seventeen periods; flow scanty; last menstruation March 8, 1909; diminished in quantity. She had one child 9 years old; forceps delivery; was confined to bed five weeks; had cholecystic infection in the puerperium and was jaundiced for three months.

Previous Illness.—The patient always had good health up to about five years before the present illness, at which time she had acute rheumatism which lasted four weeks; she had a second attack two years later. The patient was not confined to bed in either of the illnesses and did not know that the endocardium or valves were involved. Following this attack she had shortness of breath and consulted a physician who said she had heart trouble.

Present Illness.—On April 25, 1909, the patient was seized with a sharp pain in the lower part of the left side of the chest and upper abdomen, which later extended down to the pelvis. It was considered pleuritis and the patient was given opiates. The pain continued in the lower part of the abdomen after that in the upper part had entirely disappeared, which would rather controvert the idea of a splenic infarct. On April 26, between 9 and 11 a. m., the patient became nauseated and vomited five or six times; did not have a chill and did not believe she had an elevation of temperature. One hour later both the left and right legs began to pain. A physician was called, and he gave a hypodermic injection in the left leg in the region of the pain. Both legs became cold and remained so until the following morning, when the pain in the right leg ceased and it regained its normal temperature. The left leg remained cold, was blue in the thigh and very pale and shriveled in the toes, foot and ankle. It was cold to midway between Poupart's ligament and the patella. There were large blue blebs scattered over the middle third of the thigh.

Examination.—At the time of admission to the hospital the pulse was 82, respiration 26, temperature not recorded. After the operation pulse was 76, temperature 98, respiration 26. At 4 p. m., April 30, pulse 84, temperature 98.6, respiration 28. May 1, at 4 p. m., pulse 82, temperature 99.2, respiration 26. A careful examination on admission showed that the patient had a mitral, direct and regurgitant murmur. Examination of blood showed 15,400 leucocytes; hemoglobin, 85 per cent. There was no pulsation in her left femoral artery. The upper margin of the area of demarcation that appeared then was about four inches below Poupart's ligament. The limb was undergoing dry gangrene, due to ischemia from arterial obstruction. The patient was immediately taken to the operating room and it was decided to remove the embolus that was occluding the iliac artery.

Operation.—(2:30 p. m., April 29.) The patient was placed on the table with the hip slightly elevated. Nitrous oxid was given for thirty seconds, while an incision four inches long was made downward from an inch above Poupart's ligament parallel to the femoral artery. It extended through the skin and connective tissue. The anesthesia was then stopped, the dissection continued and the femoral artery was exposed for a distance of 2½ inches. It was edematous, easily freed from neighboring structures and two provisional catgut ligatures were thrown around it with an aneurism needle but were not tied. These were used in

preference to the Crile clamp so as to aid in elevating the artery, which was then incised for one inch parallel to its long axis. It was completely thrombosed. With a delicate forceps the clot (a bifurcated plug an inch and a half long) was drawn from below upward, when fresh arterial blood came from below, evidently collateral, through the femoral profundus. A finger was then placed on the lower end of the vessel inside the ligature loop, as shown in the illustration, so as to compress it and stop the return blood and still not injure the intima. With a delicate forceps I began extracting the clot from the proximal side; the artery did not empty. A delicate spoon was then introduced and more clot withdrawn, but no arterial blood came. Then a No. 6 soft catheter was introduced; it passed up a distance of seven and a half inches and was withdrawn filled with grumous, bloody debris, but no arterial blood followed. It was reintroduced but could not be forced through

Location of the clot and direction taken by the sound shown schematically.

a resistant body at that point. An ureteral catheter was then inserted; it met resistance at the same distance as before, but was forced through the thrombus and passed up nineteen inches, thus catheterizing the abdominal aorta. A small quantity of arterial blood followed its withdrawal. A uterine sound was then introduced. At a distance of seven and one-half inches it met resistance. It was forced a half inch farther, and on its withdrawal a large quantity of grumous, thrombotic debris came, but no arterial blood. It was pushed a little farther on and met a firm resistance. No blood followed its withdrawal. It was introduced for a third time, and with a little additional force at eight and one-half inches it seemed to pass through into a free space. This was followed by an intense arterial flow, causing with it a lot of

embolic debris and fresh, bright blood. The arterial flow had then all the pressure and quantity of a normal femoral artery. The finger was then inserted in the ligature loop on the proximal side to stop the bleeding. With a fine silk suture on a full curved conjunctival needle a rapid continuous suture of the linear incision in the artery was made. On removing the digital pressure it oozed a little between the second and third stitches. Two additional supporting stitches at this point completely controlled the hemorrhage, and pulsation could be felt throughout the vessel. Unfortunately this operation was four days after the embolus was arrested in the common iliac just below the bifurcation of the aorta. The skin was necrotic and the limb cold to eight inches above the knee.

Postoperative History.—After the patient was removed to her bed she complained of pain and burning in her toes and ankle, the first sensation she had had in any of those parts since the onset. Considering the ease with which this clot was removed from the second inch of the common iliac artery, it is very much to be regretted that operation was not performed early in this case and in all of these cases. The operation was done without an anesthetic practically, and can be done painlessly with a little cocaine or salt solution injected into the skin. The collateral circulation was evidently making a great effort to establish itself, for as soon as I removed the plug from the junction of the deep and superficial femorals in the lower portion of Scarpa's triangle, the blood returned from the distal side. The suture of an incision in an artery is as simple as the suture of an intestine, if a sufficiently small needle be used. This I demonstrated in 1896, at which time I made the first successful end-to-end union of an artery that had ever been made, excising half an inch of the femoral artery at about the same point where I incised it to-day. At the line of demarcation the circulation was improved immediately after the re-establishment of the flow, becoming well marked a considerable distance lower: the amputation was made four days later four inches below the line of bleb formation that existed at the time the embolus was removed, and the flap survived. The circulation in all the smaller vessels at the line of amputation was fairly well established, but the trunk of the femoral was occluded by a loose, non-adherent clot, showing that it was the result of the suppression of the circulation from below or backing up of the blood which caused the thrombus, and not an inflammatory condition.

In cases of aseptic embolism immediate removal by division of the artery at the line of the embolism or below it should be resorted to. These emboli produce mere mechanical obstruction and the circulation is at once re-established by their removal.

The symptoms which indicate the occlusion of a large artery are, first, pain; second, ischemia of the limb; third, cooling of the surface; fourth, absence of pulsation in the arterial trunk. The number of hours that may elapse before a tissue becomes incapable of restoration has not been definitely determined, but from the length of time a constrictor may be kept on a limb for the suppression of hemorrhage and the vitality of the limb restored, we know that many hours of complete suppression of the circulation is not incompatible with restoration of the life of the tissues.

Since 1896 I have had two additional end-to-end sutures of arteries, one of the femoral in Scarpa's triangle for a bullet wound, and another of the first portion of the axillary just below the clavicle. In both end-to-end union was effected by my suture method and the circulation in the extremity promptly restored. A little over five years later all three of these end-to-end unions were examined by Dr. Neff and the circulation in the extremities was found perfect. I have also had a lateral suture of the external iliac and axillary arteries with good results. In September, 1908, a successful end-to-end anastomosis was made of the femoral artery into the femoral vein for endarteritis obliterans.

Since I published my original experiments and results in this line and demonstrated the feasibility of this work, Payr, Hoeffner, Exner, Ullman, Carrel, Guthrie and others have supported the practicability of arterial suture and demonstrated that extremities and organs can be transplanted and the circulation maintained, if accurate suture of the arterial and venous trunks is made. The transplantation of organs must adapt itself best to embryologic ectodermic and endodermic glands, as their function is essentially a cellular one and not materially dependent on nerve supply, just as in horticulture the product of the graft depends on the "epithelial" cells in the bud, and these are maintained through nutrition derived from the engrafted trunk, the "epithelial" cell producing its normal or physiologic product.

In the removal of septic infarcts there is little to be gained in a practical way, as they are usually multiple. With the infarcts resulting from acute or chronic vegetations on the cardiac valves, good results should be obtained. Even cerebral ischemia should be amenable to this treatment, when due to an embolus arrested in the common or internal carotid by opening the common carotid and aspirating through a catheter; or a subclavian clot by incision of the axillary artery.

I believe that aspiration through a catheter is a better means of removing the plug than the one which I adopted. If the catheter is divided on the slant with its end open it can be readily introduced into the artery; unless the embolus is extremely hard it can with suction be drawn into or fragmented by the catheter and thus the artery freed.

Incision into the artery at the seat of arrest of the embolus, if it has been there for any length of time, is not an advisable procedure, as I found in my experiments that when a thrombus rested any considerable time on the intima it roughened it and increased its tendency to subsequent thrombosis. Therefore, the artery had better be divided above or below (preferably the latter) the point of impaction of the embolus. A gradual occlusion of the circulation does not produce gangrene in the extremity. In the British Museum are specimens showing that in gradual occlusion of the thoracic and abdominal aorta by cicatricial masses an abundant collateral circulation was developed sufficient to compensate for the occluded artery. It is the sudden ischemia that causes the gangrene.

The curved needle of the conjunctival type, which has its cutting edge easily rubbed off on a whetstone, is a good type of needle for deep work. A straight needle is difficult of insertion, and an "extremely fine needle" is not a *sine qua non* to arterial suture. After the removal of the Crile clamp or the digital compression there is often considerable oozing through the stitch holes. A gauze compression for thirty or forty seconds will completely stop all this bleeding. Silk should be used and not animal suture, as a clot rapidly forms around the silk, plugging the stitch hole.

The diagnosis of embolism of the mesenteric artery has never been made early enough to have this procedure available as a life-saving measure, but let us hope. Here, as in other types of emergency surgery, the operation must be timely in order to be successful. This applies particularly to the cerebral ischemias. The removal of an embolus from the pulmonary artery by Trendelenburg, while it terminated fatally, deserves special mention.

100 State Street.

Clinical Notes

FAVUS TREATED BY BACTERIAL INOCULATIONS

PRELIMINARY REPORT OF A CASE

G. A. PERSSON, M.D.
MOUNT CLEMENS, MICH.

This case of *tinia favosa* is perhaps particularly interesting, because, so far as my knowledge goes, there is no case of favus on record in which the opsonic treatment has been used.

Patient.—When the patient first came to my office, which was about Oct 3, 1908, he presented a classical picture of the disease. The eruption, which is shown in Figures 1 and 2, was very extensive. The lower extremities were affected in the same proportions, particularly below the knees. The nails on both fingers and toes were also involved, which gave the patient continual annoyance. The characteristic "mouse" odor was evident. The patient's general condition appeared about normal. For twenty-three years he had suffered continually without any relief, except for very short periods of slight improvements during the first three years of the disease.

Fig 1.—Patient with *tinia favosa*, from photograph taken before beginning of treatment

Examination.—Microscopic examination of the scales revealed the presence of the *Achorion schonleinii*. It was decided to isolate the specific fungus of this disease and prepare a bacterial vaccine from it. A culture from the scales planted on agar and grown in the incubator for seventy-two hours gave the characteristic culture, microscopic examination of which revealed a mixed culture of the *Achorion schonleinii* and *Staphylococcus aureus*.

A CORNEAL CURETTE

JOHN M. WHEELER, M.D.

NEW YORK

The instrument shown in the accompanying illustration may be used for curetting the cornea in any condition in which curetting is indicated, but its chief field of usefulness is in the removal of foreign bodies. Both edges are ground sharp, and the end of the instrument is ground to a point which projects a little beyond the shank. The construction of the curette is such that in its use the field of operation is not hidden from the surgeon. Most foreign bodies can be removed from the cornea without difficulty with the cutting edge of the instrument, and the foreign bodies almost invariably

stay on the curette. Occasionally a small bit of emery or like material penetrates the cornea to such a depth that the use of a sharp-pointed instrument is indicated. For this reason a point is supplied on the curette, and in using this point the shank of the instrument acts as a guard, so that there is no danger of perforating the cornea in removing foreign particles.

On account of its safety this little instrument will appeal especially to the general practitioner who of necessity must often remove foreign bodies from the eye.

64 West Fortieth Street.

Therapeutics

CHRONIC BRONCHITIS

Forchheimer, of Cincinnati, thoroughly discusses this troublesome disease in the *American Journal of the Medical Sciences*, February, 1909. He believes that the patient who has marked exacerbations in cold weather or has a prolonged winter cough should, if possible, go to a warmer climate during the cold season. This is especially advisable in cases in which there is an intermittence of the bronchial catarrh during the warm seasons, because many times chronic bronchitis begins as a recurrent winter cough which persists, until finally, it becomes an all-the-year cough. Like all recurrent inflammations and neuroses, the more frequently it occurs or the longer that it has lasted, the more persistent is the condition, consequently, every effort should be made to prevent a prolonged winter cough.

Of course, the most frequent cause of such a recurrent cough is latent or more or less active tuberculosis, but chronic bronchitis without tuberculosis while not of common, is certainly not of infrequent occurrence. If there is any season of the year that is worse for such patients than any other, it is the windy, dusty period of early spring, when there is but little, if any snow in the Northern and Eastern United States, and when it is a little too cold to sprinkle the streets properly, or the city authorities are careless in not beginning the sprinkling of the streets early in the season. Dust is certainly an exciting cause of the bronchitis, and also such dust carries with it germs which easily produce

infection, when deposited on mucous membranes that are so unhealthy as are the bronchial mucous membranes of these patients. Also, most of these patients become more or less debilitated by the cough and expectoration, and are susceptible to other infections, especially of the upper air passages.

It is too often forgotten in the treatment of chronic bronchitis that though the cough and expectoration is the most important symptoms and the one for which the patient desires treatment, a careful investigation into his general condition, and treatment aimed at his general health will cause more improvement than the administration of expectorants, either sedative or stimulant. Generally, however, some expectorant may be advisable. In this form of bronchitis, opium, or any of its derivatives, is rarely indicated as a sedative, as the cough is usually for the purpose of removing the secretion in the bronchial tubes, and a sedative, or anything that would diminish the irritability of the nerves so that the secretion would accumulate and not be expectorated, would be inadvisable and contraindicated. Also, ipecac, alkalies, and pilocarpin, mentioned by Forchheimer, are rarely indicated in chronic bronchitis. Ammonium chlorid for its stimulant action in causing the mucous membrane to secrete a healthy mucus may for a short time be of advantage, but should not be used too long, as it sooner or later causes nausea and disturbance of the stomach.

In certain cases, some of the aromatic expectorants as turpentine, benzoates, eucalyptol, and santal oil may be of benefit to the patient. Creosote or some of its many preparations may be of value, but most of these drugs, if administered for any length of time, cause indigestion, and, if there is any kidney disability, many of them are contraindicated.

Terpin hydrate is often the best and simplest drug to administer.

If an asthmatic condition be present with the bronchitis, potassium or sodium iodid becomes the best treatment.

Circulatory debility should certainly be treated. Strychnin alone will often do these patients good. Arsenic in small doses is sometimes of advantage.

Forchheimer believes that there is no doubt that some of the aromatic oils, when inhaled from proper inhalers, are of great value.

He also calls attention to the posture treatment when profuse bronchial secretion tends to remain in the bronchial tubes, and would gradually raise, little by little, the foot of the bed of such a patient, until the head is distinctly lower than the feet. He finds by experience that the first elevation of the bed at the bottom should be about two inches; later this may be increased to four or five inches. If there is one particular part of the lung where the secretion accumulates, such a side posture as will facilitate the flow of this secretion toward the larger tubes and thus promote expectoration, may be adjusted by pillows or bolsters.

In fetid bronchitis, creosote, thymol, oil of eucalyptus, or oil of pine inhalations are of benefit. Also the administration of creosote and of santal oil internally seems to be of benefit, but the more thoroughly the dilated bronchi are evacuated of their secretions by posture, the less odor will the expectoration have. Also, such patients with fetid bronchitis should, if possible, sojourn for some time in pine woods.

It should not be forgotten that these patients in some instances have combined with the necessary cough an entirely unnecessary one, a cough that raises nothing and is due to throat irritations, often to an enlarged and irritated lingual tonsil. Such a cough can be more or less controlled by the patient, if he is told that it is almost unnecessary, and may also be markedly helped by a few daily local applications of boroglycerid to the lingual tonsil. Soothing alkaline gargles will relieve this kind of a cough, which should not be treated by sweet, irritating, or nauseating expectorants.

Forchheimer well says that the best climate, or the best "cure," to which the bronchitis patient should be sent is determined by the individual condition of that patient. While one patient had best go to New Mexico, another had best take a sea voyage; while one needs circulatory and skin stimulation at some sanatorium or hot springs, another needs exercise and mountain climbing.

As Forchheimer suggests, and as has been pointed out by others, there can be no question that we do not frequently enough teach these bronchitis patients respiratory exercises.

Patients with some arteriosclerosis do well on small doses of iodid, given for long time. Other patients need sufficient daily exercise to cause profuse perspiration.

EPILEPSY

Lest too much reliance be placed on the administration of drugs in this disease, it is well for us to consider the statements made by Dr. William T. Shanahan, assistant physician at the Craig Colony for Epileptics, Sonyea, N. Y. (*The Dietetic and Hygienic Gazette*, March, 1909). He says that the three great essentials in the management of epilepsy are the diet, hygiene, and occupation, and that it is only after these have been arranged to the best possible advantage of the patient that medicinal treatment is to be considered.

To ascertain the best diet for the individual epileptic, the gastric and intestinal digestive powers should be thoroughly investigated, and to do this properly, the twenty-four hours' urine and the feces should be carefully examined. Such examinations, at least if several times done, will disclose many errors in metabolism, which may be prevented by treatment, management, or a radical change in the diet. The digestive system being made as perfect as possible, the toxins that so often are the instigators of epileptic attacks will not form, be absorbed, and circulate in the blood. Not only should the kidneys and intestines be made as nearly as possible perfect excretory organs, but the skin should be made as active as possible by massage and exercise.

Of course all epileptics should avoid alcohol, and often tea and coffee. Rich, greasy, highly seasoned foods, or indiscretions as to amount, should not be allowed to occur in the dietary of an epileptic, and special care should be exercised that the epileptic receives nothing but the freshest and most properly cooked food.

If, in spite of corrections in the diet, intestinal fermentation and putrefaction occur, the various culture preparations of lactic microbes may be administered, or yeast often acts to advantage in preventing such intestinal conditions. Radical changes in diet—from a mixed diet to a vegetable diet, or to a milk diet, or to a temporary buttermilk diet—may aid in eradicating the disturbance in the intestine.

Constipation should certainly never be allowed in epileptics, and drugs may be administered to prevent it, if must be, although of course it is best to prevent constipation by diet, exercise, and by drinking plenty of water. The best laxative, if one must be given, must be determined by the individual patient. If, in spite of ordinary laxative drugs or laxative treatments, the feces tend to remain long in the intestines, active catharsis with calomel or castor oil must be caused periodically. With such persistent constipation the advantage of the administration of sweet oil, and of the high injection into the colon of warmed sweet oil should be remembered.

Shanahan says that for the control of the epileptic seizures, bromin or its salts still hold an important place. He does not state which bromid he prefers, but sodium and potassium are probably the best. If plenty of water is drunk to make the skin and kidneys active, if the bowels move well daily, and if the skin is properly bathed, and good, healthy out-door exercise is taken, the disturbing symptoms of bromism will not develop, especially as the large doses once given have been found unnecessary. If salt (sodium chlorid) is more or less thoroughly removed from the diet, it has been found that the bromin salt, perhaps preferably sodium bromid, takes its place, and less bromid is needed to control the frequency of the epileptic seizures. Shanahan cautions not to stop suddenly the administration of large doses of bromids.

He also states that if the excretory organs of the patient are kept active, the condition of status epilepticus, or rapidly repeated seizures of epilepsy, will not occur; hence the prophylactic treatment is the best. Such a condition, however, being present, he says that chloral hydrate must be used; it is best given by enema and its retention may be aided by laudanum. He does not say how much is generally needed, but states that it should be used with caution, and exhaustion guarded against by the use of stimulants such as aromatic spirits of ammonia, and enemata of strong black coffee, at a temperature of from 100 to 105 F. If needed, he would also give physiologic saline solution intravenously or by hypodermoclysis, and if there is much cardiac depression he uses strychnin, digitalis, and strophanthus.

At the onset of the status epilepticus, gastric and intestinal lavage are often of value. Venesection may be used in plethoric cases, and lumbar puncture has been tried, but with only questionable success. If the epileptic seizures are rapid and severe, chloroform inhalations may be administered until the chloral has had time to absorb from the rectal or colon injection.

Of course in treating any individual epileptic, an attempt should be made to correct any physical disability that may be present. Adenoids and enlarged tonsils should be removed; decayed teeth should be cared for; eyes should be fitted with glasses, if they require it; hemorrhoids should be removed, if present; pelvic disturbances in females must be prevented, medicinally, if may be, or operatively if must be.

Shanahan does not speak of the disturbances of menstruation being a frequent cause of epilepsy in girls and women, nor of the advantage of the administration of thyroid both as an emmenagogue and as a preventive of nitrogen poisoning. It is a fact that many female epileptics may be greatly improved and even cured with general management and the proper administration of thyroid.

AORTITIS, AORTIC ENDOCARDITIS AND SYPHILIS

With the development of two new diagnostic criteria of syphilis, the Wassermann reaction and the finding of spirochetes, it has been possible to approach the so-called parasyphilitic diseases from a new ground, with the result of brilliantly confirming the conclusions previously reached by clinical observation. As the parasyphilitic affections are late manifestations or results of syphilitic infection, and for the most part not accompanied by definite syphilitic lesions, the search for spirochetes has not been of much help in their etiologic determination, since these organisms are usually found with difficulty in even the most typical lesions of the tertiary stage. With the help of the Wassermann reaction, however, it has been demonstrated that the relationship between syphilis and such diseases as tabes and general paralysis is fully as frequent as the clinicians have long believed, and if anything more so. The variations in the results obtained by the laboratory investigators who have applied the serum test to these diseases, are about the same as we have been accustomed to see reported by clinicians who were endeavoring to establish a relationship on the basis of clinical history and coexisting syphilitic manifestations.

Among the parasyphilitic lesions degenerative and productive changes in the aorta, with resulting aneurism or aortic insufficiency, have long presented problems to the pathologist and clinician of great practical as well as theoretic interest. Even Ambroise Paré, Morgagni and other early masters of medicine recognized that syphilis played an important rôle in the etiology of arterial diseases, but we owe especially to the work done under Heller at Kiel our present understanding of the characteristic features of aortic syphilis. Now it is generally recognized that fleshy nodular thickenings of the aorta, most abundant in the ascending part, and frequently extending to the aortic valves with resulting incompetence, are commonly of syphilitic origin, especially when they concern individuals in the prime of life. Microscopically, these lesions are found to involve chiefly the media and adventitia, consisting of foci of round cells in the vicinity of the vasa vasorum, while in the media may be found foci of necrosis which sometimes are typically gummatous in character. As a rule, the histologic features of these lesions are not such as to prove

conclusively their syphilitic origin, and consequently the pathologists have discussed at much length the proportion of such aortic lesions that should be ascribed to syphilis, and the possibility of similar lesions being produced by the acute infectious diseases. It seems to be generally accepted, however, that the most usual cause of such changes in the aorta is syphilis, although it is possible and probable that they are not by any means specific evidence of syphilitic infection. In other words, their status is just about the same as that of tabes and paresis in respect to etiology. Mönckeberg found that of the reported cases of aortitis 33 per cent. showed positive evidences of syphilis, while in a further 44 per cent. other parasyphilitic affections coexisted. Chiari reported that of 27 cases of undoubted syphilis examined post-mortem aortitis was present in 16, and of 44 paralytics 21 showed aortitis, indicating that more than one-half of all syphilitics coming to autopsy show characteristic lesions in the aorta. Similar results have been obtained by clinical observation. In v. Strümpell's clinic of 24 cases, tabes and aortic lesions, chiefly aortic insufficiency, coexisted in 15.

For some reason the application of the serum test to aortic disease has lagged behind its use in the study of nervous cases, but the results that have now been obtained are fully as convincing, and perhaps even more valuable from the therapeutic point of view than the results in tabes and paralysis. Fränkel and Much first applied the Wassermann test to the blood from cadavers showing aortitis with aortic insufficiency, and in all the six cases examined the reaction was positive. Citron¹ has studied systematically, by the serologic method, with interesting results, all the cases of aortic insufficiency coming to Kraus' clinic in Berlin in the past year and a half. Although only 14 per cent. of all cases of uncomplicated aortic insufficiency gave definite, and a further 26 per cent. suggestive, clinical evidence of syphilis, yet no less than 62.6 per cent. gave a positive serum reaction.

The earlier attempts to locate spirochetes in the aortic lesions resulted for the most part negatively, so that the positive findings reported by Schmorl, Reuter and Benda were accepted with more or less skepticism in view of the possibilities for error that the degenerated aortic tissues offer to the searcher for spirochetes. However, now that Wright and Richardson² have reported the finding of structures morphologically identical with *Spirochæta pallida* in all of five cases of aortitis examined by them, there will be no hesitation in the acceptance of these positive findings by Americans who are familiar with the splendid technic of the Boston laboratory.

All the above findings taken together would seem to prove finally the importance of syphilis in the etiology of the nodular form of aortitis which is so frequently

1. Berl. klin. Wehnschr., 1908, xlv, 2142.
2. Boston Med. and Surg. Jour., 1909, clx, 529.

associated with insufficiency of the aortic valves. Indeed there seem to be relatively few cases of simple aortic insufficiency that are not due to syphilis, especially if we exclude those cases where there is a history of rheumatism. As the Wassermann test seems to have distinct value in indicating the activity of syphilitic lesions, there would seem to be an excellent opportunity for therapeutic advance in the treatment of aortic regurgitation when of syphilitic origin, as most of the uncomplicated cases are shown to be.

RELATION OF HUMAN AND BOVINE TUBERCULOSIS

We are approaching the end of the solution of a problem which for many years has been the subject of bitter controversy and during the past eighteen years has been the object of perhaps more extensive work than any other in medicine. The relation of human and bovine tuberculosis is a question of first importance and deserving the most careful consideration.

The investigations which have led up to the proof of the intercommunicability of the disease in man and cattle may be divided into three periods: first, those taking place before the publication, in 1882, of the discovery of the tubercle bacillus by Koch; second, those occurring between the time of the discovery of the tubercle bacillus and its differentiation into human and bovine types by Theobald Smith in 1896-1898; third, those occurring since the establishment of these two types.

During the first period, it was shown by direct experiment that cattle could, though with difficulty, be infected with tuberculous material of human origin; their resistance to the human virus is so great, however, that it is unlikely that the infection occurs naturally.

Evidence of infection from tuberculous cattle to man could not, of course, be sought experimentally, but numerous observers collected statistics which furnish much circumstantial evidence that not infrequently man is infected with the virus of bovine tuberculosis. Numerous cases were studied in which, among children especially, the disease was in all probability caused by consumption of milk from tuberculous cows. A smaller number of cases, but cases furnishing more conclusive proof, were those in which direct inoculation occurred, as in those cases where tuberculous lesions followed wounds received by veterinarians and butchers while handling tuberculous meat.

The evidence obtained during the second period, that is, after the discovery of the tubercle bacillus, differed but little from the preceding, except that the demonstration of the bacilli made the diagnosis more certain, and its cultivation in pure culture gave a greater value to the direct inoculation experiments in animals. This circumstantial evidence was so convincing that it would doubtless have served to bring about the observance of adequate precautionary measures had it not been for the spirit of controversy which existed.

The discovery of the two types of tubercle bacilli, human and bovine, made possible the solution of the problem. On the basis of this distinction the German commission, the British commission and a number of individuals have proved that bovine tuberculosis is communicable to man. In over 300 cases reported in the literature in which the determination of the variety of bacillus present has been made, bacilli of the bovine type have been found in over 60 cases, a little more than 20 per cent. This can not be taken as representing the true incidence of bovine infection in man, since in some of the series investigated cases were chosen in which it seemed especially probable that the infection was of bovine origin. The results indicate clearly, however, that bovine tuberculosis is a source of danger to man sufficiently great to demand rigorous precautionary measures against it.

To arrive at a more accurate knowledge of the incidence of infection with the bovine type of bacillus in man, a great number of cases of tuberculosis, including the various forms of the disease, must be brought under investigation.

It will be of great interest and importance to see if certain forms of tuberculosis are constantly associated with one or the other type of bacillus. It is already evident that the bovine bacillus rarely, if ever, produces pulmonary tuberculosis. On the other hand, it has been found in a considerable number of cases of cervical adenitis and tabes mesenterica, as well as in other forms of tuberculosis.

The bearing which the type of bacillus present in a given infection will have on the therapeutic treatment of the case is not yet clear. In most of the work which has been done on the immunization of cattle against tuberculosis, living but attenuated cultures of tubercle bacilli of the human type have been used; there have been a few experiments, however, which indicate that vaccinations with attenuated cultures of bovine bacilli are more potent to protect cattle than are the vaccinations with the human bacilli. This fact may become significant in the treatment of human tuberculosis. Although at present there is but little to indicate that tuberculins prepared from the two types of the bacilli differ essentially, yet individuals with tuberculosis who had received one kind of tuberculin over a long period of time without evident benefit sometimes show a definite and progressive improvement when a change is made to tuberculin produced by the other type of bacillus.

Whether this result depends on the type of bacillus present in the infection has not been investigated, nor have we enough evidence to say whether we should use the homologous tuberculin or vaccine or the heterologous ones, but in the present unsatisfactory state of the therapy in tuberculosis, advantage should be taken of these points if any advantage lies in them. Further investigations are required along these lines.

THE ANTITOXIN UNIT AS A MEASURE OF CURATIVE
VALUE

While most of the active workers in the field of immunization have believed that the curative value of a serum could be accurately gauged by the number of antitoxin units it contained, there have not been lacking some dissenting voices. As is well known, the content of a serum in diphtheria antitoxin units is determined, as a rule, by mixing measured quantities of the serum with a standard toxin and injecting the mixture, under carefully controlled and uniform conditions, into a guinea-pig of 250 grams weight. The degree of protection afforded by a given serum under this procedure is generally considered to indicate its relative value for curing diphtheria in man. That is to say, if 10 c.c. of 200-unit serum proves efficacious in curing a patient, just one-half the amount, or 5 c.c. of a 400-unit serum should prove equally efficacious.

Roux, Cruveilhier and others were among the first to report findings at variance with this conclusion. According to these observers, the dose of diphtheria antitoxin which has the greatest therapeutic effect is not always the one that contains the greatest number of antitoxic units. If this be true, the inference would seem to be justified that the antitoxin is not the only important preventive and curative substance in the serum. Steinhardt and Banzhaf,¹ on the other hand, after a careful repetition of Cruveilhier's experiments, arrived at diametrically opposite results. They found no evidence that the therapeutic power of a serum was dependent on anything except the number of antitoxin units it contained, and they conclude that the present method of standardizing antidiphtheritic serum accurately measures its therapeutic value.

The question has also been investigated more recently by Kraus² of Vienna, who has obtained results similar to those of Roux and Cruveilhier. Kraus studied not only antidiphtheritic serum, but also antidysenteric serum and the antitoxic cholera serum (*el Tor vibrio*). With all of these he found that no fixed relation existed between the amount of antitoxin and the curative value of the antitoxic serums. As a rule, his experiments showed that the "high potency" antidiphtheritic serums (from 300 to 600 units) possessed a relatively lower curative power than those of less antitoxic concentration (from 100 to 150 units). Kraus is inclined to attribute this phenomenon to a difference in the "avidity" of the antitoxin in different serums. In the discussion following Kraus' paper, Kretsz stated that the clinical results with the high potency serums, as he had observed them in a Vienna hospital, were less satisfactory than those with the low potency serums in which, of course, a greater bulk of serum was used. It should be noted that this is contrary to the recorded experience in the New York hospitals and elsewhere in this country.

Part of the discrepancy between the conclusions drawn by Kraus and those of Steinhardt and Banzhaf may be explained by the different modes of experimentation employed by these investigators, but that this is the sole factor concerned in bringing about the divergence seems hardly probable. Kraus expresses his conviction that the problem of measuring the curative value of a serum is not solved and that a re-examination of the whole subject is urgently needed.

DISSEMINATION OF FOOT-AND-MOUTH DISEASE BY
VACCINE VIRUS

The statement¹ from the Bureau of Animal Industry of the Department of Agriculture in Washington concerning the source of the recent outbreaks of foot-and-mouth disease in Michigan, Pennsylvania and other states is of special interest. A new, hitherto apparently unsuspected source of this disease has been discovered, namely, lymph from vaccine calves. This discovery with its important practical consequences and the whole outcome of the investigation outlined in the statement are highly creditable achievements both to the Bureau of Animal Industry and to the U. S. Public Health and Marine-Hospital Service. The manufacturers in question participated with commendable zeal in carrying out the radical measures instituted by the government in order to rid the market of the unwittingly contaminated vaccine by recalling all the virus on the market.

That the virus of foot-and-mouth disease could exist undiscovered for so long a time in calves used for the production of vaccine virus is not at all incredible in view of the fact that the company from which the original contaminated vaccine came killed its calves so soon as their yield of virus was collected. It was only when the used calves were returned to the market that the infection began to spread.

Discovery of the actual agent of foot-and-mouth disease in contaminated vaccine by any other method than animal experiments is out of the question, because it concerns an agent that is not visible or cultivable by our present methods. Being a filterable virus, that is, passing through filters that hold back ordinary bacteria, it is commonly spoken of as an ultramicroscopic virus. Hence the presence of the virus of foot-and-mouth disease in vaccine lymph can not possibly be detected by the routine methods ordinarily employed to test the purity of vaccine lymph. Under the circumstances it was a matter of good fortune that human beings are relatively but little susceptible to foot-and-mouth disease and apparently not at all when the virus is applied as in vaccination; were it otherwise there surely would have resulted a large number of human cases. As it is, not a single case appears to have developed.

While the cost of this outbreak of foot-and-mouth disease has proved to be no small item, it is a great

1. Miscellaneous Department in this issue of THE JOURNAL

satisfaction to know that through efficient governmental agencies has the outbreak not only been definitely overcome, but also that such knowledge has been gained as will prevent future outbreaks from this source.

VALUE OF STATE BOARD STATISTICS

We present this week for the sixth consecutive year tabulated statistics based on examinations conducted by state medical licensing boards during the past year. These statistics appear on pages 1691 to 1713 and are worthy of careful study. The four large tables, A, B, C and D, give the results in detail, while the others are presented to bring out the more important deductions.

These statistics, while they should not be taken alone in passing judgment on any medical school, constitute a very important part in the investigation of medical colleges and throw much light on several factors having to do with medical education. In the lists of medical schools shown in Tables I, J and K, with a very few exceptions, the classification is surprisingly upheld by the extended investigation and inspection of medical colleges made by the Council on Medical Education.

Occasionally a college may be listed in Table I, when in justice it should not appear in the better class of colleges. These apparent discrepancies are due to the character of the state board examinations as they are generally conducted and which can frequently be passed by graduates of colleges which give no laboratory or clinical training. Meanwhile, since we began publishing these data six years ago, some colleges have been able to lower their failure percentages considerably by giving special state board quizzes, without in any way improving their equipment for teaching. These methods of cramming for state examinations, however, will probably be corrected through the adoption of practical tests which are already being required by several boards and which will doubtless soon be generally adopted. That state boards are becoming more careful at their examinations is shown by the increasing percentage of failures from 19.1 per cent. for all candidates in 1904 to 21.7 per cent. in 1908 and by the number of colleges having less than 10 per cent. of failures being reduced from 64 in 1907 to 48 this year.

An important fact drawn from Table B is that over 64 per cent. of the graduates of medical colleges become licensed in the states wherein the colleges are located, and the percentage is really higher for colleges of inferior grade. Thus a state is not only responsible for the existence of any low-grade medical schools, but is itself the recipient of the greater part of the poorly trained graduates of those schools, and the standing of the profession as a whole in those states will be correspondingly impaired.

That seven states together registered 213 undergraduates during 1908 is shown by Table M. The number of such candidates registered will be greatly reduced, however, since three of the states, Alabama, Arkansas and Rhode Island, have recently secured legislation demanding that all candidates be graduates of reputable medical colleges. We urge that these statistics be given a

careful study, especially by those who are interested in the problem of medical education and medical licensure.

Thanks are hereby extended to the various licensing and examining boards for their cooperation in the work of compiling these statistics.

Medical News

ARKANSAS

Commencement Exercises.—The thirtieth annual commencement exercises of the Medical Department of the University of Arkansas, Little Rock, were held April 30, when a class of 22 was graduated. The diplomas were awarded by Governor George W. Donaghey, and the address to the graduates was delivered by Rabbi Louis Witt.—The third annual commencement exercises of the College of Physicians and Surgeons were held in Little Rock, April 29, a class of 14 receiving diplomas. The faculty address was by Dr. C. T. Drennen, Hot Springs.

Personal.—Dr. Claude E. Laws, Fort Smith, has been appointed a member of the State (Eclectic) Medical Board, vice Dr. Jacob F. Lewis, Little Rock, resigned.—Dr. Joshua C. Sexton has been elected president, and Dr. Henry E. Thomason, a trustee of the newly-organized antituberculosis society at Siloam Springs.—Dr. Charles A. Archer, DeQueen, has been elected delegate from the Sevier County Medical Society to the state medical society, and Dr. R. H. Hopkins, DeQueen, and Oliver O. Hammonds, DeQueen, were named as alternates.

Society Elections.—Clark County Medical Society, at its annual meeting in Arkadelphia, April 29, elected Dr. E. Kindle Williams, Arkadelphia, president; Dr. John H. Cuffman, Gurdon, secretary-treasurer, and Dr. James C. Wallace, Arkadelphia, delegate to the state society.—Logan County Medical Society, at its meeting in Paris, April 16, elected Dr. Early E. Scott, Magazine, president; Dr. M. E. Foster, Roseville, vice-president; Dr. John S. Shibley, Paris, secretary-treasurer; Dr. Samuel P. McConnell, Booneville, delegate to the state society, and Dr. Will H. Bennett, Paris, alternate.—At the annual meeting of Polk County Medical Society, held in Mena, April 17, the following officers were elected: Dr. Andrew J. Pool, president; Dr. William C. Vandiver, vice-president; Dr. Frank A. Lee, secretary; Dr. Philip R. Watkins, treasurer, and Drs. William P. Parks, Philip R. Watkins, and Columbus C. Gunnels, censors, all of Mena.—At the annual meeting of Conway Medical Society, held in Morrilton, Dr. Frank Gordon, Morrilton, was elected president; Dr. J. F. Halbrook, Cleveland, vice-president; Dr. George W. Ringgold, Morrilton, secretary-treasurer and delegate to the state society.—Howard County Medical Society, at its annual meeting in Nashville, elected the following officers: Dr. William H. Toland, Mineral Springs, president; Dr. David A. Hutchinson, Nashville, vice-president; Dr. Jesse S. Hopkins, Dierks, secretary; Dr. W. M. Gibson, Nashville, delegate to the state society, and Dr. James M. Daly, Nashville, alternate.—At the annual meeting of Boone County Medical Society, held at Harrison, Dr. R. S. Grebs, Olvey, was elected president; Dr. Alfred M. Hathcock, Harrison, vice-president; Dr. J. L. Sims, Harrison, secretary; Dr. Hugh L. Routh, Batavia, treasurer, and Dr. Frank B. Kirby, Harrison, delegate to the state medical society.—At the annual meeting of Garland County Medical Society, held in Hot Springs, April 7, the following officers were elected: Dr. Morgan F. Mount, president; Dr. Elmer H. Ellsworth, vice-president; Dr. John S. Wood, secretary; Dr. Joseph S. Horner, treasurer; Drs. Eugene C. Hay and Randolph Brunson, delegates to the state society, and T. Earl Sanders and Linda H. Barry, alternates, all of Hot Springs.—Independence County Medical Society, at its annual meeting in Batesville, April 5, elected the following officers: Dr. Charles G. Hinkle, Batesville, president; Dr. William T. P. Huddleston, Sulphur Rock, vice-president; Dr. Oscar J. T. Johnston, Floral, secretary-treasurer and alternate delegate to the state society; and Dr. Robinson C. Dorr, Batesville, delegate.

COLORADO

Personal.—Dr. T. Clarkson Taylor has been appointed health officer of Fort Collins.—Dr. Albert W. Rew has been appointed city physician of Fort Collins, vice Dr. Wilbur O. Upson.—Dr. John R. Espey, Trinidad, is said to have been sustained in his contention that Dr. Alfred Freudenthal has

fessor of medical jurisprudence. The faculty then met and elected the following officers: Dr. Montague J. Lowry, president; Dr. T. Alexander Barber, dean; Dr. Nathan L. Clark, vice-president, and Dr. John R. Tackett, treasurer.

NEW JERSEY

State Society to Meet.—The Medical Society of New Jersey will hold its annual meeting at Cape May, June 23-25.

Society Meetings.—At the annual meeting of Mercer County Medical Society, held in Trenton, May 11, the following officers were elected: President, Dr. Charles H. Mitchell; vice-president, Dr. Gustave A. Schoening; secretary, Dr. Edgar L. West; treasurer, Dr. Iranaeus M. Shepherd; recorder, Dr. Charles J. Craythorn, and delegates to the state medical society, Drs. William S. Lalor, George N. J. Sommers, and Paul L. Cort, all of Trenton. —Salem County Medical Society, at its annual meeting, held in Salem, May 5, elected the following officers: President, Dr. John M. Summerill, Penn Grove; vice-president, Dr. George W. Fitch, Daretown; secretary-treasurer, Dr. Henry Chavanne, Salem; reporter, Dr. John F. Smith, Salem; censors, Drs. William H. James, Pennsville, Frank B. Harris, Canton, and Richard M. Davis, Salem, and delegates to the state medical society, Eugene E. DeGroot, Woodstown, and Lester H. Hummel, Salem.

NEW YORK

Site for Insane Hospital Again Opposed.—It is announced that the State Commission in Lunacy had chosen a new site for the proposed asylum at Farmington, L. I. With the announcement that an offer for property had been accepted, the same opposition that was raised in connection with the Grenvale purchase is met. The citizens of Farmington in a mass meeting filed a protest with the governor, the senator, assemblymen, and lunacy commission, against the location of a hospital for the insane at or near the village.

Bills Signed.—Governor Hughes has signed the following bills: Senator Platt's, providing that any person knowingly bringing a domestic animal suffering from an infectious or contagious disease into the state shall be liable to all damages caused by the spreading of such disease; Senator Raines', relative to quarantine for rabies, posting notices and providing a penalty for destroying such notices while they are in force; Representative Shea's, providing that the state shall pay 50 per cent. of the appraised value of an animal condemned for glanders; Representative Boshart's, giving the chief veterinarian of the State Department of Agriculture the same authority to quarantine on account of contagious diseases, as is now held by the assistant commissioners, and also providing for a more stringent labeling of articles termed in the agricultural law "concentrated commercial feeding stuffs," and Senator Newcomb's, rearranging the control of infectious and contagious disease hospitals in New York City as between the various city departments devoted to this work.

New York City

New Training School Opened.—The formal opening exercises of the New Bellevue Training School for Nurses were held April 28. The building is located between East Twenty-fifth and Twenty-sixth streets, and cost about \$1,000,000.

Hospital Suspends.—The Brooklyn Memorial Hospital for Women and Children has been closed because the work of the institution has been so seriously handicapped by the lack of facilities. Arrangements are being made for the erection of a new structure which it is hoped may be erected in two years. The Memorial Dispensary which has been connected with the hospital has been removed to Sterling Place.

To Help the Blind.—The New York Association for the Blind recently gave a benefit at the Hippodrome where between five and six thousand dollars was raised. In connection with the entertainment was an exhibition demonstrating the various kinds of work that could be done by the blind. The association asks \$100,000 as a permanent fund to carry on its work and already has \$85,000 pledged on condition that the remaining \$15,000 be raised.

Enlarge City Hospital.—Plans have been filed for the erection of a two-story and attic pathologic laboratory building as an annex to the Metropolitan Hospital, Blackwell's Island. The main floor will contain the offices, the museum and specimen room and a room for autopsies; the second floor will be fitted as a library and with laboratories for microscopical, chemical and bacteriological research, and also a special private laboratory for the surgeons and the attic will be fitted as a menagerie for animals for experimental use. The structure will cost \$40,000.

United Hebrew Charities May Get Million.—The \$1,000,000 left to the United Hebrew Charities on condition that an agency should make collections for the six charities and that the funds should be distributed among them by Louis A. Heinsheimer, is still in the hands of Alfred M. Heinsheimer, as several of the institutions refused to accept the terms of the will. A meeting was recently held at which a thorough canvass of the situation was made and a resolution was passed calling for the appointment of a committee to consist of one person from each of the six institutions and each of these to choose three additional persons. The testator desired this plan of cooperation in order to reduce the expenses of collection.

NORTH DAKOTA

County Medical Society Organized.—The Richland County Medical Society was organized at Wahpeton May 3. Dr. Martin W. Ivers, Abercrombie, was elected president; Dr. Robert H. Devine, Wahpeton, vice-president; Dr. Timothy O'Brien, Wahpeton, secretary; Dr. Louis W. Meckstroth, Wahpeton, treasurer, and Dr. Charles P. Spottswood, Hankinson, censor.

State Association Meeting.—The annual meeting of the North Dakota Medical Association was held in Fargo, May 11 and 12. The following officers were elected: President, Dr. John E. Countryman, Grafton; vice-presidents, Drs. Henry H. Healy, Grand Forks; N. Oliver Ramstad, Bismarek, and Louis W. Meckstroth, Wahpeton; secretary, Dr. Hezekiah J. Rowe, Casselton (reelected); treasurer, Dr. J. Dempsey Taylor, Minot (reelected); delegate to the American Medical Association, Dr. Victor H. Stickney, Dickinson; alternate, Dr. Zella W. Stewart, Grand Forks, and councilors, Drs. P. J. Artz, Jamestown; Charles McLachlan, New Rockford; R. W. Pence, Minot, and Edgar A. Pray, Valley City. Grand Forks was chosen as meeting place for 1910.

OHIO

Will Not Prescribe Liquor.—The Wyandot County Medical Society, at its meeting April 29, adopted a resolution that its members refuse to furnish prescriptions for intoxicating liquors until, after having made a personal examination of each patient, it is deemed that the stimulant is necessary.

Sanatorium Dedicated.—On May 1, the Brookside Sanatorium, Dayton, was formally presented to the local tuberculosis society by E. B. Markey, who, in his address, dedicated the institution to the cause of bettering the condition of unfortunate consumptives. Rev. William A. Hale delivered an address on the "Great Cause of Tuberculosis." The sanatorium is located within six miles north of Dayton, and the buildings consist of a two-story brick house, and several structures erected on plans approved by the International Tuberculosis Congress.

Cincinnati

Fresh Air Society.—At the annual meeting of the Fresh Air Society it was announced that the society expected to care for from 2,000 to 3,000 on its farm near Terrace Park, during the coming season, and a plea was made for funds for this purpose, for the painting of cottages, fitting up the dining room, and constructing cement walks, for all of which \$1,100 is needed.

New Plans for Interns Examination.—A new plan for the examination of internes has been adopted in Cincinnati. Four hospitals consented to hold a single examination under the auspices of the staff of the Cincinnati Hospital, the successful candidates being allowed to select the hospital in which they prefer to serve, the selection to be made in order of rank. There were 23 who passed the examination, but as there were only 20 positions to fill, 3 will act as alternates.

PENNSYLVANIA

Personal.—Dr. and Mrs. William G. Miller, New Castle, will sail for Germany early in June. —Dr. Ernest L. Clark has been elected president of the Media Free Library Association.

Appropriations Cut.—Governor Stuart reduced in general the appropriations to the state and semi-state institutions recommended by the legislature. The appropriations to these institutions, however, are higher than they were two years ago.

Food Bill Approved.—Governor Stuart approved the Todd-Murphy Food Bill, May 13. The act is now in force, previous conflicting statutes being repealed thereby. This act permits the use of benzoate of soda and sulphur dioxide as preservatives. A long list of preservatives is forbidden by the act,

including boron compounds, pyroligneous acid, salicylic acid, formaldehyd, sulphate of copper, alum and many others.

Portrait of Dr. Agnew Unveiled.—On May 13, a portrait of the late Dr. D. Hayes Agnew was unveiled at Mercersburg Academy. The members of the Franklin County Historical Society and the medical societies of Mercersburg, Chambersburg and other towns in Franklin county attended the ceremony. The address was delivered by Dr. J. William White, professor of surgery in the University of Pennsylvania.

Tuberculosis Society Directors Elected.—At the annual meeting of the Pennsylvania Society for the Prevention of Tuberculosis, held in Philadelphia April 14, the following directors were elected: Drs. Howard S. Anders, Frank A. Craig, J. Clinton Foltz, Albert P. Francine, C. Lincoln Furbush, William D. Robinson, Jr., William C. White, T. Mellor Tyson, J. Willoughby Irwin, Henry D. Jump, and J. Gurney Taylor, Philadelphia, and Dr. Charles H. Miner, Wilkesbarre.

Bill Vetoed.—Governor Stuart has vetoed the Blewitt bill, which requires all state or other hospitals in the state receiving annual appropriations from the state to furnish to sick or injured firemen, either permanent or volunteer, caused by exposure or accident while in the performance of their duties, a private room or rooms, together with all medical attention, board and supplies, free of charge. The Governor said that there appears to be no occasion for such legislation, and that therefore the act is not approved.

Philadelphia

City to Give Milk to Babies.—The Department of Health and Charities is prepared to distribute free milk and ice to babies during the hot months of the summer. This is the first time that the city has undertaken to supply milk to the children of the poor.

Health Bureau Chief Resigns.—Dr. Alexander C. Abbott, chief of the bureau of health, has resigned his position to take effect June 1. He will devote his time to his work at the University of Pennsylvania and will have charge of the laboratory of hygiene and physiology.

Educational Tuberculosis Exhibition.—An educational tuberculosis exhibition by the Pennsylvania Society for the Prevention of Tuberculosis, was opened in the Auditorium of the Kensington Young Men's Christian Association, May 17, and will remain five days. Demonstrations are being given each day and preventive measures for combating the disease are being outlined.

Lectures to Mothers.—At a conference, May 13, between the Director of Public Health and Charities, and Mrs. Frederick Schoff, president of the Mothers' Congress, arrangements were made for a series of lectures to mothers on the care and treatment of infants. The lectures will be delivered in the public schoolhouses after school hours by the assistant medical inspectors and nurses connected with the health bureau.

WASHINGTON

First-Aid Equipment for Schools.—The Seattle board of education has ordered that first-aid cases, blankets and hot-water bottles be installed in all school buildings having domestic science departments. The cost of this equipment will be a little less than \$600.

Hospital Notes.—Work will soon commence on the hospital to be erected by the Sisters of Charity between Jefferson and James streets and Seventeenth and Eighteenth avenues, Seattle. The building will be of steel brick and concrete construction, six stories in height, and will cost about \$250,000.

—Physicians of Bremerton have raised \$1,100 by popular subscription to purchase a site for a hospital for Kitsap county. The building proposed will cost about \$7,000.—Plans for a three-story addition to the Hoquiam General Hospital to cost about \$10,000, have been prepared, and construction work will soon be begun.—The Emergency Hospital, Seattle, on the fourth floor of the new Municipal Building, was officially opened March 31, when 19 patients were transferred to the hospital. About \$125,000 has been spent on the new hospital, which is under the direction of Dr. James E. Crichton, commissioner of health, assisted by Drs. Frank S. Bourns and Inslee B. Greene.

WISCONSIN

Home for Consumptives.—Plans are being made in Milwaukee for the construction of an isolation hospital for consumptives at Wauwatosa, on a site purchased three years ago for \$32,000. The principal building on the ground will be remodeled to conform to the modern ideas of open-air treatment, and eventually smaller cottages will be erected for the use of patients.

Personal.—Dr. Adelbert Schneider, Milwaukee, has returned from Europe.—Dr. Lawrence P. Mayer, Hudson, is seriously ill with septic pneumonia.—Dr. A. D. McKinley has resigned as house surgeon at the Johnston Emergency Hospital, Milwaukee, to become superintendent of the Fox Lake Sanitarium.—Dr. James W. St. John, Janesville, has been appointed fire and police commissioner.

GENERAL NEWS AND COMMENT

Vanderbilt Alumni Meet.—The alumni of Vanderbilt University Medical Department, Nashville, Tenn., will have their headquarters at Young's Hotel at Atlantic City during the meeting of the American Medical Association, and on June 8 a banquet will be given at the hotel at 8 p. m.

Meeting of Milk Commissions.—The third annual meeting of the American Association of Medical Milk Commissions will be held June 7, at the St. Charles Hotel, Atlantic City. The association now has a membership of 48 milk commissions. Proceedings of the 1908 session will be mailed in a few days.

Internists Elect.—At the annual meeting of the Association of American Physicians, held in Washington May 11 and 12, the following officers were elected: Dr. Henry Hun, Albany, N. Y., president; Dr. Frederick Forchheimer, Cincinnati, vice-president; Dr. George M. Kober, Washington, secretary; Dr. Solomon Solis Cohen, Philadelphia, recording secretary; Dr. J. P. Crozer Griffith, Philadelphia, treasurer, and Dr. Henry Sewell, Denver, counselor.

Gastro-Enterological Meeting.—The twelfth annual meeting of the American Gastro-Enterological Association will be held at Atlantic City at the Hotel Windsor, June 7 and 8. The address of the president, Dr. Julius Friedenwald, Baltimore, will be on the "Development of Gastrology," and in the evening of the first day a symposium on "Gastro-Enterostomy," participated in by Drs. W. B. Cannon, Fred T. Murphy, and Franklin W. White, Boston, Henry W. Bettmann, Cincinnati, and John M. T. Finney, Baltimore.

Laryngologists to Meet.—The thirty-first annual congress of the American Laryngological Association will be held in Harvard Medical School, Boston, May 31 to June 2, under the presidency of Dr. Algernon Coolidge, Jr., Boston. The entertainment includes a luncheon given by the Boston members to the fellows and their ladies and the president's reception on the first day; a luncheon given by the Boston members of the American Otological Society and the American Laryngological Association to visiting fellows and the annual dinner on the second day. On the third day the Otological Society and Laryngological Association discuss nasal and pharyngeal conditions as causative factors in aural diseases.

The Carroll Fund.—The following subscriptions have been received since the last report:

From Medical Officers of the Army.....	\$ 20.00
Dr. F. W. Taylor, Paaulo, Hawaii.....	5.00
Medical Society, Sioux County, Iowa.....	11.00
Dr. A. de Bey, Orange City, Iowa.....	
Dr. G. A. F. de Lespinasse, Orange City.....	
Dr. C. de Jong, Orange City.....	
Dr. A. L. Druet, Boyden, Iowa.....	
Dr. N. G. O. Coad, Hull, Iowa.....	
Dr. D. J. Gleusteen, Alton, Iowa.....	
Dr. G. Marris, Hull, Iowa.....	
Dr. F. L. McAllister, Hawarden, Iowa.....	
Dr. C. S. McCarthy, Hawarden, Iowa.....	
Dr. H. D. Oggel, Maurice, Iowa.....	
Dr. D. J. Werkman, Secretary, Hull, Iowa.....	
Kansas State Medical Society, Columbus, Kansas.....	55.50

\$ 273.00
Previously acknowledged 3,825.65
Total \$4,098.65

The sum of \$3,326.50 is still needed to raise the mortgage on this property. Remittances should be sent to Major Ireland, care Surgeon-General's Office, War Dept., Washington, D. C.

Tropical Medicine.—The Far Eastern Association of Tropical Medicine will meet in Manila, P. I., March 6-14, 1910. The session will open at Manila. On the second day protozoology and helminthology will be considered; on the third day, cholera, plague and leprosy; on the fourth day, surgery, obstetrics and diseases of children; on the fifth day, fevers in the tropics, including malaria, typhoid, etc.; on the sixth day, dysenteries and beriberi; on the seventh day, the association will go to Baguio, Benguet, the summer capital of the Philippines, where tuberculosis, climate, hygiene and sanitation will be discussed.

long into clinics and operative surgery, receive lectures on lectures on symptoms and diagnosis, with little stress on the gross pathology and none on the microscopic pathology. This is partly because it is presumed that that knowledge on the subject has already been imparted to the students and that they are, therefore, familiar with it. At times it may possibly be because the active surgeon has acquired, by long experience, that intuition in surgical diagnosis and interpretation which unconsciously results from and finally supplants that pathologic knowledge which he formerly had, but which has become somewhat hazy with the mist of time.

These are conditions which are perfectly natural and to be expected, but nevertheless not to be desired. The student mind, immature in medical conceptions, is unable properly to grasp and to correlate these two great and useful subjects and thereby acquire with the material already at hand and at his disposal that knowledge which has taken many of his predecessors years to acquire through varied and often bitter experiences and sad mistakes. It is this training in the correlation of the great subjects of pathology and physiology with medicine and surgery which has developed the vast majority of our world-renowned diagnosticians, surgeons and clinicians. It is not the art of surgery which has accomplished the greatest wonders, but it is the science of accurate diagnosis and interpretation which has raised surgery to the high pinnacle of to-day.

It is this breach in the teaching of the medical schools that surgical pathology tries to fill. There is much that it does do and still more that it might try to do, but one object it certainly endeavors to attain, and, if that is accomplished, the failures may be considered as atoned for. It endeavors to teach the student never to think of any one phase of the subject to the exclusion of the others, but continually to correlate his knowledge of anatomy, physiology and pathology and to make it applicable to the subject at hand. It endeavors to show that symptoms are merely effects which must follow definite underlying pathologic, physiologic or anatomic derangements and that clear and comprehensive understanding of the conditions to be dealt with necessarily means a clear conception of the gross or minute processes which are occurring beneath the superficial coverings of the skin and tissues. It endeavors to develop in the student "the microscopic eye" so that when he is called on to study a case he may quickly call to mind the possible morbid processes with which he may be dealing and the necessary morbid effects that they would produce and, by exclusion, arrive at an accurate diagnosis with its proper and scientific treatment.

As to the practical methods used to carry out these ideals, they may be many and varied. That which appeals most to me and which I have endeavored to carry out as far as possible is somewhat along the following lines. First, there should be a close and definite relationship between the departments of surgery and surgical pathology so that those in the department of surgical pathology shall have the freest access to all the surgical cases, on whatever service they may be, in order that they may be fully informed as to the history and progress of every operative case within the hospital. They should be informed in advance of every operation to be performed and as far as possible should participate in the operation so as to have that intimate knowledge of the conditions which comes only with sight and touch, at close quarters. Every specimen removed from the living body, no matter how trivial or unimportant

it may appear grossly, should be sent, either immediately in the fresh state or carefully preserved in whatever form of preservation may best suit the laboratory chief, to the laboratory for examination. Every single specimen should be carefully and accurately labeled, and with each specimen should be sent a slip, giving all the important data pertaining to the case. Preferably, it should be accompanied by a copy of the full history. These histories should be filed away and indexed so as to be immediately available to any one studying the specimen.

When specimens are received in the laboratory, they should be immediately carefully described, photographed when possible or drawn if of sufficient value; then a section removed for microscopic examination and the remainder prepared by Kaiserling or other method for permanent mount. The histories, with photographs, negatives and pathologic reports, should be filed away in large envelopes so that at a moment's notice all the available data may be at hand for a careful study of the case as a whole. For the same reason all the specimens in the laboratory should be cross-catalogued in three different manners, viz.: according to the name of the patient, according to the organ or region affected, and according to the nature of the affection. Choice typical specimens should be sectioned, stained and mounted for class laboratory work, and at times it may be of advantage to teach from specimens which are not typical if thereby some point in diagnosis may be more forcibly brought to the front. At this period in the course I do not think it fair to the student to require him to spend valuable time sectioning and staining specimens; I believe that his time should be devoted to more careful study of them with a view toward the practical application of his knowledge in the wider subjects of surgery. As many of the specimens, while valuable from the teaching standpoint, are not always available when desired, and since but a very small minority of the students ever look at their slides again after leaving college, it has not been my practice to give these slides to the students, but to use them year after year until they are destroyed by breakage, etc. Usually there will be sufficient of the specimen so that slides may be presented to a few of the more interested of the students should they desire them. The classes can easily be accommodated if the student be given an individual tray accommodating five or more different slides for the day's study. So much for the conduct of the laboratory and the preparation for the course.

The course itself should be placed as near to the end of the college curriculum as is possible, so that it may go hand in hand with the advanced teaching in surgery and at the same time better prepare the outgoing student to take up his work in hospitals, army, navy or other advanced training ground. It should consist of both lectures and laboratory work. The lectures should be illustrated by lantern slides, by patients, specimens and illustrations whenever possible, in order to treat thoroughly the theoretical portion of the subject and in order to assemble all the essential facts from the correlated branches in so far as they are related to the subject in hand. The laboratory work is intended for a careful study of microscopic slides illustrating the various phases of the affection just lectured on. The laboratory work should be made to coincide as much as possible with the lectures so that the full force of whatever may be taught can be realized at the same time. This

work can be further helped by making this course coincide, when possible, with the lectures on surgery.

The subjects to be taught and the order and manner in which they shall be approached are matters on which all may differ and still attain good results. I have found the old method followed in the teaching of surgery, according to systems, very satisfactory and see no reason to change. I usually begin by considering the fundamental essential for surgery, namely, regeneration and repair in the various character of tissues: then I take up the diseases of the skeletal system, the surgical affections of the gastrointestinal system from the lips to the anus, including the gall bladder and pancreas, the thyroid gland, the genital system in male and female, including the breast, the surgical affections of the urinary system and, finally, the lymph system and miscellaneous conditions, as skin tumors, etc.

In treating all these subjects, whenever time will permit, a very hurried survey is first made of the anatomy, histology and physiology of the organ or region to be studied in order that the student may have at hand all the data necessary for the proper application of his pathologic knowledge to the study of the living patient. The pathology of the condition and the latest experimental findings are then gone into as carefully as possible with especial stress on their relationship to other organs and the region affected when such relationship exists. Methods of transference of conditions with routes, whenever traceable, are studied in detail, as in the case of metastasis of tumors, etc. Symptoms and recognized methods of treatment are touched on only when there is a pathologic lesson to be derived or when their own origin is easily and distinctly traceable to some plainly demonstrable macroscopic or microscopic pathologic condition. In other words, the student's attention is called to symptoms only when necessary to show how clearly dependent they are on abnormalities of structure, causing abnormalities in physiologic function. He is not required to know them as forming a clinical entity, but whenever possible an effort is made to make it easy for him to conjecture as to their presence from a simple process of deductive reasoning. The whole subject is then clinched by a couple of hours spent in the laboratory studying microscopic and gross specimens covering the subject considered.

This I submit as my answer to the query. "What is surgical pathology?" The subject as a distinct specialty is comparatively young, and courses in the various colleges are of very recent date. We feel that with proper encouragement both by students and co-educators much good can be accomplished for the student, his burdens made lighter instead of increased, his mental attitude toward medical subjects broadened, and at the same time there will develop a set of men trained in experimental surgery and pathology, well equipped to take up the burdens when time shall rob us of the masters of to-day.

2131 North Fifteenth Street.

Carbohydrates in Diabetes.—I. V. Lemann, in the *New Orleans Medical and Surgical Journal*, April, states that each case demands separate study, because cases differ not only in grade but in kind also. The tolerance of patients to various carbohydrates is different. Various complications call for alterations in diet, and unless the physician is prepared to give intelligent attention to these details he can not hope for good results from the diet he prescribes for his diabetic patients.

CANCER OF THE BREAST

F. S. DENNIS, M.D.

NEW YORK

In the present contribution, I shall refer only incidentally to statistics. In several previously published papers¹ I have given my statistics at length. I desire now to express some opinions that I have formed and facts that I have collected from a study of my own personal cases during the past twenty-five years, selecting a few cases of cancer of the breast, and analyzing them critically, because I believe it is a better way to arrive at the truth, than by a promiscuous study of a large number of cases with statistics only as a guide to determine certain important facts.

I intend to consider very briefly some salient facts in regard to the final outcome of thirty-nine cases of cancer of the breast, the histories of which I know from the time of the operation to the present day. These thirty-nine cases have been selected from a large number solely for the reason that I have a personal knowledge of each case from the incipency of the disease to the present moment. All these patients have lived beyond the three years' limit of time. One patient has lived twenty-five years, another nineteen years, another seventeen years, and another fifteen years, and the rest from three to fourteen years with no return of the disease. In this list one was eighty-five years and another eighty-two years old. I mention these two cases to illustrate the fact that age itself appears to offer no barrier to an operation for the relief of cancer of the breast.

I am convinced that a study of the cure of cancer of the breast from a percentage point of view only has created a very false impression among surgeons and a depressing effect on the laity. The all-important question for the surgeon and the patient is this: Can a permanent cure be effected if the operation is undertaken early, and radical in character? If this view can be substantiated it will create hope in the patient, and inspire courage in the surgeon.

The clinical picture of cancer of the breast has been so drawn in past years as to create a most unfavorable impression. The early and radical operation is certain to efface this gloomy picture, and to draw in its place one that will inspire hope in the unfortunate victims of the disease. The safety of the operation is a subject worthy of consideration. In all of the operations which I have mentioned, and an accurate knowledge of which I possess, there has not been a death except in two cases of hemophilia, and such deaths are not peculiar to this special operation, but would occur in connection with any other major operation. The mortality therefore, in several hundred cases would be almost nothing, even if these cases were included, and absolutely nothing if they were excluded. The percentage of permanent cures, on the other hand, can not be so correctly estimated because so many cases are lost sight of and therefore can not furnish data for statistical purposes. In a recent small series of cases extending over three years from the time of the operation the percentage of permanent cures amounted to 77 per cent. In a previous series the percentage was 45 per cent., but these operations were done earlier in the history of what is called the complete operation. The sum total of percentages of cure therefore, would fall below the high figure previously mentioned, and above the lower figure stated in the second series. These facts certainly en-

courage the surgeon to hope for even better results, and as we learn more about the disease and still further improve the technic of the present operation, the future holds out even greater encouragement for more brilliant results in the cure of a disease, which in former years baffled the skill of the greatest surgeons of the day.

PERMANENT CURE

The permanent cure of cancer of the breast is a subject in which the surgeon as well as the patient take the greatest interest. All other subjects, such as etiology, diagnosis, operation, and the like, are insignificant to the patient as compared with that of the permanent cure.

What constitutes a permanent cure? Authorities differ on this question. No one is willing to admit a less time than three years as decisive. Recently some surgeons have placed the limit of time as five years. In some of my cases ten to eighteen, and even twenty-five years have elapsed with no return of the disease.

The percentage of returns after three years is so insignificant that it would seem wise for surgeons to accept this standard, not only for the encouragement of the patient, which is no small fact in the management of the disease, but because it establishes a fixed standard from which the case from an operative as well as an optimistic point of view can be judged.

ADVISABILITY OF OPERATION IN ADVANCED CASES

There is much diversity of opinion on this question. From my own experience I feel certain that it is a wise course to operate unless the mediastinal glands are involved, or unless there is visceral metastasis, or the growth is adherent to the chest wall. I have been astonished at some results after operation, in cases in which I felt absolutely certain a return and death would follow in a few months. Yet these patients have recovered and have remained free from the disease for years, and thus have demonstrated the error of a too conservative view held by the profession at large.

In some cases in which the outlook was most unfavorable, as manifested by extensive ulceration, hemorrhage, wide-spread axillary involvement, the final results have been entirely satisfactory. No better proof of this statement can be made than by a brief reference to three cases occurring in the list of thirty-nine cases of cancer of the breast. It seems pertinent to call attention to these three cases because they demonstrate the possibility of a cure when everything looked hopeless. I admit that we can not place much reliance on a cure when cases present such a chain of unfavorable symptoms. It only shows that surgeons should not withhold an operation from the patient, even when the outlook is most discouraging. The patients should have the benefit of the doubt; it is always best, however, to explain to the friends the situation, and then they will not be too greatly disappointed if the operation is attended with a quickly fatal result.

The first patient had a foul, ulcerating, hemorrhagic, and fungous breast, with axillary enlargement. I advised the operation, not with the expectation of curing the disease, but purely from an humanitarian point of view. I felt sure that the hemorrhages could in a measure be controlled, the offensive smell to a greater or less extent be removed, the constant pain, at least for a while, be relieved, and the patient be made more comfortable during the few months she lived. To my surprise after nine years this patient has been free from

the disease, and to all intents and purposes is at the present time in perfect health. The operation was radical as the circumstances permitted, and I am at loss to explain the cure under these unfavorable conditions.

The second patient was the victim of a fungous, hemorrhagic foul-smelling carcinoma of the breast. I hesitated to operate at all, but did so at the request of the husband, with a full understanding that the operation was one to palliate the distressing symptoms, and with no expectation of cure. This operation was performed five years ago, and only recently the patient died from an acute disease, with no evidence of any return of the cancer.

Both of these tumors were examined by microscopists of world-wide reputation, who pronounced them carcinoma. I merely mention these two cases in the list of thirty-nine to illustrate the fact that sometimes recovery takes place in the most hopeless cases. Such instances appear to me to urge the surgeon to operate in the most desperate cases, with the most forlorn prognosis, unless, as previously indicated, there is involvement of the mediastinal glands, or visceral metastasis, or adhesion of the growth to the chest wall. I can offer no explanation as to the behavior of these two tumors, but they both seem worthy of record as evidence that our knowledge is still incomplete in regard to the course of certain types of cancer of the breast.

The third case is one in which I had operated nearly ten years ago and later a metastasis occurred in the lung with an extensive hemothorax. By aspiration a very large quantity of bloody fluid was withdrawn to relieve a severe dyspnea. To my utter astonishment, this patient, after the paracentesis, began immediately to improve from an almost bed-ridden condition, and for many years was in fairly good health and was in the habit of coming to my office from a distance for two or three years. From a study of these cases, bearing on the subject of permanent cures, I have been impressed with the fact that the histologic formation of the tumor influences in a marked degree the question of permanent cures. For example, I have found that the tumors which show structures departing but slightly from the normal, correspond in nearly every case with the group of cases, the clinical histories of which were favorable, because in these cases no return of the carcinoma occurred. The tumors that showed a great departure from the normal structure occurred in the cases with unfavorable clinical histories. The more typical the structure, therefore, the more favorable the prognosis; the more atypical, the more unfavorable the prognosis. In other words, epithelioma develops by asexual cell proliferation; the more embryonic the cell is, the more malignant the growth; and the nearer the cell approaches the normal, the less malignant the growth.

CONDITIONS REQUIRED FOR COMPLETE RECOVERY

The early and radical operation is of paramount importance, since the facts I have already mentioned clearly demonstrate the value of this rule. The early operation is indicated because glandular infection is not likely to be present, and the patient is in better physical health, from absence of worry and pain. This fact should impress the family physician with the responsibility of referring his patient early to a surgeon, who then must assume the responsibility of this important question. No growth in the breast, however small, should be disregarded, especially if the patient is ap-

proaching the menopause. It is by a view to prophylaxis that the mortality of death from cancer of the breast is to be still further reduced.

The more radical the operation, within reasonable limits, the better the prognosis. It seems unnecessary and a loss of time to discuss this point, since it is universally admitted that the more radical the operation, the less likely it is that the disease will return. The difficulty seems to be as to what constitutes a radical operation. Surgeons agree that all skin over the infected area should be sacrificed. The breast, with Sir Astley Cooper's ligaments, should be entirely removed, the pectoral fascia and muscles should be excised, the axillary glands, the perimammary and retromammary fat, likewise the paramammary areolar tissue should be dissected out as the minimum operation. If the cancer involves the ribs, perforates the thoracic wall, and has already infected the mediastinal glands, no operation, however radical, would be attended with any success. The same rule may also apply to that form of cancer termed *en cuirasse*, or *en plaques*, or acute miliary carcinoma. I am firmly convinced that any radical operation, more than has been described, will be of no avail. The element of time should be seriously considered, since the performance of any operation which requires the patient to be under an anesthetic for four or five hours, is attended with a risk, which if possible should be obviated. These prolonged operations are sometimes followed by ether pneumonia, acute sepsis, profound shock, suppression of urine, and many other like conditions, which jeopardize the life of the patient. In other words, we must not lose sight of some of the general principles connected with surgery, at the expense of the elaboration of an operation, the performance of which eliminates some of the best precepts and practices of our art.

In most of my cases in which no return has ever occurred, even though twenty-five years have elapsed since the operation, the patients, almost without exception, were operated on within six months from the first appearance of the disease. This point seems to me of the greatest importance in relation to the prognosis, and without question the earlier the operation the more certain it is that a permanent cure can be effected. At this point naturally the question arises as to a certainty of diagnosis within six months. I admit that it is often difficult to determine with absolute certainty that any small nodule in the breast is carcinomatous. The obstacle presented by the theory that a correct diagnosis of carcinoma within six months is a *sine qua non* for operative interference has been removed in my own mind, by a rule that all nodules or tumors in a breast in a woman at the time of or near to, or after the menopause, especially with a depressed nipple and skin dimpling, should be removed by a complete ablation of the breast. The risk run is too great if surgical interference is deferred until the diagnosis is made certain.

In several cases during the past few years I have adopted this procedure, and to my surprise the microscopic report has been returned with the diagnosis of incipient epithelioma. In such cases the patients do well as they are taken early in the course of the disease, and the nodule is small and surrounded by healthy glandular tissue. In the hands of a good surgeon with aseptic environment the risk of removing the breast is so slight that it may almost be disregarded as a factor in determining the question of an operation.

A point still further to consider is that in a large majority of cases in which a nodule or tumor is felt, it is almost certain in time to become malignant, if it has not already begun to undergo malignant degeneration. This same law of early surgical interference holds good in case of tuberculous induration, in syphilitic ulceration, in actinomycosis, or in other infective processes.

The question is more difficult when the patient is a young woman, and the growth is adenomatous. Such cases are more difficult to manage; but I am still of the opinion that all adenomata in the young should be removed, and in the case of very young girls only the nodule itself excised and examined, and if then found to be undergoing epitheliomatous changes, the entire breast should be removed by a radical operation. In the case of young girls or young women, the breast can be raised by a flap with an incision under the breast and in its fold, and turned on the thoracic wall, and the adenoma attacked from the posterior surface of the gland. After excision of the adenoma the breast can be turned down and sutured with the scar completely hid from view. I have done this and preserved the symmetry of the breast; and I have record of cases of this kind in which the breast subsequently performed its function of lactation.

In cases of chronic mastitis in a woman over forty, if pain is a constant factor, and the interstitial induration is marked, the breast should be removed to prevent the possibility of malignant degenerative changes. Within a few weeks I removed a breast for painful mastitis, and Dr. Norris reports that beginning epithelioma is present.

THE MANAGEMENT OF CASES THAT DO NOT ADMIT OPERATION

These are the cases that tax the surgeon's skill, and cause severe suffering to the patient. Nothing is more distressing to the surgeon and painful to the patient than to watch the progress of a fatal disease with the full knowledge of the condition—both waiting, utterly helpless, until the end comes, and death closes the scene.

In such cases the surgeon's duty is to mitigate the suffering, and to make the patient as comfortable as possible with a view to euthanasia. The different methods of treatment of cancer of the breast, in cases in which no operation is possible, can be discussed very briefly. The *x-ray* is one of the methods now in vogue. One writer has reported a dozen cases of cancer of the breast in which cures were effected by the *x-ray*. The absence of a microscopic examination of any of the tumors, and the fact that not a single case in the list had yet reached the three years' limit of time make these cases valueless as a basis on which to study results.

The *x-ray* is a force that should not be employed by one who is not an expert in its use, because its employment even by the best men has been followed by violent dermatitis, by ulcers that fail to heal, and that finally became the starting point of epithelioma. In a recent article by Pusey, some interesting clinical facts have been brought out in connection with the *x-ray*, which are worthy of mention. He thinks that the *x-ray* is not suitable for cases of carcinoma in which the adjacent lymph nodes are involved. It is also futile in cancer of the neck, or of the viscera. In recurrent carcinoma of the breast, alleviation of suffering for a few months has followed the *x-ray* treatment, but no cures have

more than one-fourth of all breast cancers. I have only once operated on mother and daughter. Both, I am pleased to say, are still living in good health, the daughter having been operated on in June, 1904, and the mother in July, 1906. The case of the latter was one of the most interesting I have ever seen, inasmuch as the removed specimen demonstrated cancer and a number of very small abscesses—which I think were tuberculous—and Professor McFarland, the pathologist, was unable to say which was the primary condition. A photograph of the specimen is shown in my book.¹ I have frequently operated on women who gave a history of cancer of the breast in their mothers and sisters, and occasionally it has shown itself in three generations—grandmother, mother and daughter.

Before leaving the subject of diagnosis, it must be candidly admitted that in about 10 per cent. of patients cancer of the breast can not be recognized clinically in its early or operable stage, for in addition to the difficulty of differentiating between solid growths, it is even more difficult to distinguish between benign and malignant cysts. This can safely be determined only by the microscope, and that it is necessary to be most careful in separating the one from the other no experienced surgeon will deny.

It is true that a bloody or sanguinolent discharge indicates malignancy, but a clear fluid does not by any means demonstrate benignity. Nothing save the microscope can positively discriminate between simple and malignant cysts. Hence, the danger of any other treatment than excision, not only of the entire cyst wall, but of enough adjacent tissue reasonably to insure eradication of the disease. I would emphasize the fact that cysts are often malignant when they would seem macroscopically, on account of their thin walls and clear contents, to be innocent; furthermore, that the degree of their malignancy is very great, so much so that a mistake made at the time of operation may not, probably will not, be atoned for by a second and more complete operation after the microscopist has made his report. In the first place, a radical second operation, even if performed within a fortnight, is likely to result in failure on account of the liberation and distribution of epithelial cells at the time of the first operation. Secondly, the patient will generally refuse a second operation; and it is most embarrassing to the surgeon to be placed in such a position. Here, as elsewhere, partial removal may do more harm than good, stimulating the remaining cells to an unwonted growth. Therefore, there is but one reasonably safe and certain method to follow in doubtful cases: the patient's consent to a complete operation should first be obtained, explaining fully that it will not be resorted to unless the microscopic examination made at the time of the operation demonstrates its necessity. The most suspicious part of the growth should be removed, along with adjacent structures if possible, and given to a microscopist who is present and who is, moreover, familiar with making reports from frozen sections. The wound should be instantly plugged with gauze, then cauterized with the actual cautery. In this way *only* will the danger of possible dissemination of cancer be minimized. I have followed this plan more than fifteen years and have known but one malignant tumor mistaken by the pathologist for a benign one. In this case the mistake was more than pardonable, although a clinical diagnosis of cancer had been made, as it was not until many sections had been cut at the second or confirmatory

examination ten days after the first operation that carcinomatous tissue was encountered. In other words, the portion of the growth first examined was benign. That at the second examination was also found to be benign, until the thirteenth section was made and examined. Figures 1 and 2, from photomicrographs of the only lobule involved, indicate the malignant change to be in its incipency. The pathologist, Dr. Wieder, thinks it as early, and therefore as favorable a case as he has ever examined. I am indebted to him for these excellent photomicrographs. The patient was advised to have and fortunately accepted the second operation.

Admitting that mistakes must occasionally occur in the hands of those doing frozen section work, it is no more than we must expect even in the less rapid and presumably more careful work ordinarily done in the pathologic laboratory; for I have known some of the very best pathologists to make mistakes and reverse themselves after several examinations of the same tumor. Only a few weeks ago I removed what I supposed to be a large sarcoma of the breast. Figure 3 shows this specimen. In ten days after the operation the report came back from the laboratory "sarcoma undoubtedly," four or five of the best pathologists in Philadelphia having examined the specimen. In fact, it was shown at the Pathological Society of Philadelphia. Several weeks afterward a second report was sent me to the effect that the tumor was also in places carcinomatous. This opinion has been expressed by pathologists of very highest standing, among the number Professor Smith of the University of Pennsylvania, and Dr. Repplier of the Presbyterian Hospital. It is only reasonable to suppose that such apparently contradictory reports must now and then result, notwithstanding every precaution to insure accuracy primarily. This is the only case I have ever encountered in which there were both sarcoma and carcinoma undoubtedly present in the same specimen. Others have reported such cases, and it explains many strange and inconsistent things in the subsequent history of cases. For instance, it explains why the secondary or daughter growth did not resemble the parent neoplasm.

COMPLICATIONS

Next to the variety of the growth, the prognosis is most influenced by the presence or absence of enlarged glands in the axilla and elsewhere. This fact has been emphasized by every writer from time immemorial. It has been made more definitely clear by the recent statistics of the Johns Hopkins Hospital² and the Massachusetts General Hospital,³ in both of which series the cases were carefully scrutinized with reference to the involvement of the axilla. In 64 of 232 patients operated on in the Johns Hopkins Hospital, in whom there were undemonstrated glandular involvement, 51 or 80 per cent. were free from recurrence at the expiration of three years. Of 110 patients with demonstrated axillary involvement, only 24.5 per cent. were free from recurrence at the expiration of three years. Of 236 patients with palpable axillary involvement, before operation, operated on in the Massachusetts General Hospital during the decennium from 1894 to 1904, only 12 per cent. were cured by operation. Of 117 patients operated on in the same hospital, in whom no glands were felt in the axilla, 29 per cent. were cured. In nearly all of the cases, even though palpable enlarge-

3. Greenough, Simmons and Barney: Tr. Am. Surg. Assn., 1907, xxv, 90.

ment of the glands was not manifest, there was found to be microscopic involvement. It is only fair to suppose that limited involvement of the axillary glands may be successfully met by operation, for in such cases the epithelial cells are confined to the interior of the glands and therefore can be entirely removed. But if there is gross involvement of the axilla, particularly if the glands have become matted and fused together, the presumption is that the capsule and tissues around the glands have also become infected and that the prognosis even after an extensive operation, must necessarily be bad. The advantage resulting from early operation, before there is palpable involvement of the axilla, and the hazard of delay until axillary involvement has taken place, could not be more forcibly shown than has been done by the statistics of two such large and representative hospitals. Moreover, the experience in these hospitals, and in all others so far as my knowledge goes, demonstrates forcibly that in cases in which axillary involvement is so great as to make

notably the skin and pectoral wall. Every surgeon has recognized the gravity of adhesion to the chest wall and the comparative futility of operation to give more than temporary relief. The statistics of the Massachusetts General Hospital, while clearly indicating this to be a serious complication, show that of 45 such patients, 5, or 11 per cent., passed the three-year limit without recurrence. Of 194 cases in which there was no adhesion to the chest wall, 41, or 21 per cent., were successful. Where the skin alone is adherent, the prognosis, while less favorable than in cases without adhesion, is better than it is where adhesion to the chest wall is present. Of 262 patients with adherent skin, only 42, or 16 per cent., were cured by operation. In 71 patients in whom the skin was not adherent, 23, or 37 per cent., were cured. Therefore, this complication is of much greater importance than it would at first seem, and its unfavorableness is easily appreciated by remembering the fact that the largest and most important of the lymph-bearing channels are found in the skin.

Fig. 1.—Specimen from malignant tumor, at first mistaken for benign growth, low-power view of only lobule involved

Fig. 2.—High power view of same acinus shown in Figure 1

resection of the axillary vein necessary in order seemingly to get beyond the encroachments of the disease, operation, though possibly prolonging life, has not resulted in a single cure. I would again insist on the fact that no one, however skilled, can always or usually recognize before operation the presence of enlarged axillary glands; and that such enlargement, though not detected beforehand, will nearly always be encountered when the axilla is carefully explored. It is certainly never safe to assume that enlarged axillary glands do not exist. In all cases, even cases of adenocarcinoma in which glandular involvement is less apt to occur than in other varieties, a thorough dissection of the axilla is just as important as removal of the breast itself. Only once have I operated for either medullary or scirrhus carcinoma without encountering unmistakable enlargement of the axillary nodes when the axilla was explored. Frequently I have failed to detect such enlargement before operation.

Next and hardly secondary in importance to involvement of the neighboring lymphatic glands is the adhesion of the growth to neighboring structures,

ENLARGED SUPRACLAVICULAR GLANDS

Palpable enlarged glands above the clavicle have always been considered by surgeons to be the gravest of complications, and practically to preclude operative relief. In fact, they have almost universally been looked on as a positive barrier to operation. While of the greatest significance, it must be remembered that such enlargement may be inflammatory. Of 40 patients with palpable neck involvement operated on in the Massachusetts General Hospital,³ 2 were found to be free from carcinomatous involvement and were well three years after operation. All of the remaining 38 cases were fatal. Of 40 operative cases in the Johns Hopkins Hospital³ with positive involvement of the neck and the axilla, 3, or 7.5 per cent. were cured. This is perhaps the best showing that can be made in this class of cases, inasmuch as the neck operation was first advised and has been insistently carried out at the Hopkins Hospital during the past fifteen years. While I have never known a patient of my own with either palpable or microscopic involvement of the supraclavicular glands to be cured by operation, I did have one

Fig. 6.—Primary skin incision.

cent. passing the three-year limit. This was the best showing, so far as I know, made by any surgeon up to that date.

These results, together with the pronouncement of Meyer and Halsted, in favor of a freer and more anatomic operation, stimulated others to greater endeavor, and, we may say, presaged the greatest advance yet made in breast surgery. At the present time it is not claiming too much to say that at least one-third of the mammary cancers which come to operation should be cured, and that early cases should give a much better prognosis — one-half or two-thirds of the patients making permanent recoveries. If the patient fortunately presents herself for operation before there is either adhesion of the skin, axillary involvement or other complication — in other words, while the disease is strictly local—80 per cent., or four out of five, should be cured.

But, taking cases as they come, early and late, we find that of 210 patients operated on in the Johns Hopkins Hospital, whose cases were traced later, 42.3 per cent. were apparently cured three years

or longer." This is the best showing made by any hospital of which I have knowledge, but no better than a number of individual surgeons have done. It is my own belief that we shall more accurately measure the true value of any operation for cancer by taking the smaller series of surgeons who are able to follow their private patients for many years after operation. It is simply impossible to trace accurately a large number of hospital cases. I have long since been made to realize the impossibility of satisfactorily doing so and, therefore, have abandoned the attempt. In the first place, one's private patients are more intelligent, seek

advice earlier, submit to operation more readily, and if told that their safety depends on regular visits to the surgeon for at least five years after operation, they will willingly do so.

I have not for many years hesitated to tell patients that they have cancer, and, in my judgment, it is a great mistake not to do so. If the advantages of an early operation and the hazards of delay are fairly placed before patients, they will rarely hesitate. Therefore, it is

Fig. 7.—Division of pectoralis major near its insertion.

much better and fairer to them to call the disease by a name which all understand and dread rather than to call it a "tumor" or a "malignant growth," the nature of which they do not apprehend. Of course, half-truths are told with the very best and most humane motives, but the whole truth very soon dawns on the unfortunate victims with appalling force, and, mayhap, when it is too late. The truth should be told delicately and with consideration, of course, but it should be told, nevertheless.

During the ten years from Sept. 1, 1898, to September, 1908, or since my removal to Philadelphia, I have certainly operated on more than a hundred patients with cancer of the breast. Of the ward patients treated in the five hospitals with which I have been connected—I estimate them at fifty or upward—very little is definitely known. Therefore, all are excluded. Of 25 private patients operated on, which includes every patient treated from 1898 to 1905, 7 are dead and 1 is living with recurrence. This patient had, at the time of operation, a very large goiter, rapid-

ly increasing in size, which she declined to have removed. Dr. Fell, of Wilkes-Barre, writes me that the goiter has further increased in volume and that the opposite breast is certainly involved to a pronounced extent. Seventeen, or 68 per cent., are living in good health without local or general evidence of recurrence.

To show that my cases were at least of average severity, two of the patients had been operated on by other

surgeons and had suffered recurrences. In one of them I was compelled to resect the axillary vein to the extent of four inches on account of extensive axillary infection. Both of these are dead. In one other case the growth was so advanced that I should very likely have declined to interfere, but for the insistence of the patient's husband, who was a physician. Both he and she declined operation when I first advised it a year before, as they were about starting to California for the winter on account of his health. Two of the 17 recovered patients had adenocarcinoma, 2 had cancerous cysts, 2 medullary, and 11 scirrhous growths. One of the cured patients had both breasts affected.

Fig 8—Division of pectoralis minor at its insertion.

Fig 9—Axilla freely exposed and vessels divided at their origin

clude every private case submitted for operation. Had the patient survived the operation, the chances of a radical cure would have been good, as the growth proved to be adenocarcinoma.

Since 1905 I have operated on a larger number of private cases than in the preceding seven years, and many of the patients have gone long enough to convince me that the end-results will be at least as good if not better than in the series herein reported.

My method of operating has meantime changed somewhat, all the while tending to become more radical. Two years ago I definitely abandoned all flap operations as being at least potentially dangerous. They are alluring and seductive, inas-

much as they often facilitate the closure of a wound otherwise difficult; but that they may do so to the prejudice of an abiding result there can not be the slightest doubt. He who always begins and ends his incision in the same manner for a disease so protean in its manifestations and so widely variant in its local ex-

An interesting and encouraging feature of the series is that two of the cured patients were operated on during pregnancy. Both went to term. Patient 14, whose case was fatal, also had pulmonary tuberculosis. Cancer and tuberculosis rarely coexist, this being the only time

I have encountered it. This was a patient of Dr. P. S. Donnellan, now residing in San Diego, Cal.

The patients whose cases are of longest standing were operated on January, 1899, May, 1900, December, 1900, and November, 1902, respectively. All are perfectly well. Figure 4 is from a photograph of the last, on whom a double amputation was done. Skin grafting was done on the right, but not on the left side.

I may add that one patient, a woman, aged 77, with a very bad heart, died suddenly within a week after the operation. As this case has no possible bearing on the subject of ultimate result, it is only mentioned for the reason that I wish to in-

FIG. 10.—Axillary dissection completed. Fascia, fat and enlarged glands en masse shown at base of axilla. External respiratory, or nerve of Bell, shown on the inner wall of the axilla. Subscapular nerve on the posterior wall. Sheath covering all muscles removed.

pressions will in time necessarily be disappointed and chastened, if not disheartened utterly. If anything has been demonstrated, it is that recurrences generally manifest themselves in the skin, and that its wide removal is the prime consideration, even though the necessarily large wound made must be closed by either undermining or skin grafting.

The operative mortality was less than 1 per cent. in 2,133 operations performed by 25 American surgeons who do a very extensive operation. The radical procedure is just as safe as incomplete operations — I believe safer, because it permits accurate work in the axilla. Much of the previous heavy mortality from breast operations resulted from hemorrhage, shock and sepsis, due to wounding the vessels, especially the axillary vein, on account of an attempt to clear out the axilla through an inadequate wound.

Fig. 12—Undermining inferiorly. Muscles, breast and axillary mass being reflected prior to removal.

TREATMENT

There is but one treatment for cancer of the breast—operation—and the earlier and more radical the procedure the better.

The chances of a cure in any given case depend almost wholly on the timeliness and manner of operating. It should be unnecessary to point out the futility and harmfulness of local applications, caustics, radium and x-rays. All are time-consuming, none of demonstrated value; consequently they should not be used until after operation has failed, or possibly as an adjuvant to it in well-selected cases. Hence, it is necessary only to consider a few of the more prominent and basic principles in the operation for breast cancer. A large wound, removal of the pectoral muscles, a thorough axillary dissection *en masse*, are theoretically admitted to be necessary by practically all advanced surgeons. A few who do not remove

Fig. 13—Appearance of the wound after removal of the breast, muscles and axillary mass. A small part of the origin of pectoral muscles left as a covering for the ribs. This very much facilitates grafting, when necessary, which is rarely the case. In fourteen operations during the winter it has been necessary in only two cases.

reality is most obnoxious, and that to overcome infection traveling from breast to liver the sheath over the upper part of the rectus should be removed. I was so impressed with his views set forth at Oxford before the British Medical Association in 1904, where we appeared jointly in the discussion of cancer of the breast, that I at once began enlarging my wound internally, making a freer dissection of the epigastric triangle and removing the sheath of the rectus in all cases when the tumor involves the sternal hemisphere, especially its lower quadrant. I have always believed and frequently insisted on it previously that growths involving the inner half of the breast are deadlier than are those of the outer

Fig. 14.—Wound being sutured. Middle third of horizontal incision may be, if necessary, covered by skin-grafting. It is rarely necessary. Latterly the drainage tube at either end of horizontal wound is omitted

the muscles cut across and retract the ends, so as to uncover the axilla, subsequently suturing them. A smaller number, I think, practice removal of the fasciae covering the subscapular, serratus, latissimus and other muscles exposed in the axillary dissection; and still

hemisphere. The latter metastasize to the axilla, where it is possible for us to pursue and destroy the enemy; but the former metastasize to the liver, mediastinum, lungs, sternum, ribs or vertebrae—all veritable Gibraltars—defying surgical attack by either assault or siege.

fewer continue the incision far enough internally and inferiorly to expose the sheath of the rectus in the epigastric triangle. Almost none remove it. The investigations and teachings of Mr. Handley,¹⁰ of London, indicate that carcinoma spreads peripherally by permeation of its epithelial cells along the deep fascial planes, hence the reasonableness of removing fasciae possibly infected. Mr. Handley also insists—and he has much to support his contention—that abdominal metastases are more frequent than thoracic ones and instead of the lungs being most often the site of secondary foci, as we formerly believed, the liver in

10. Cancer of the breast and its operative treatment, John Murray, London, 1906.

The following is a brief report of a case occurring in my practice:

Patient.—Mrs. H. of Walton, Ind., a patient of Dr. Carpenter, was operated on for gallstone disease on March 19. The symptoms which had led the family physician to the diagnosis of gallstones were those which are observed usually in such cases. There had been present gallstone colic, left-sided pains (suggestive of adhesions between the pylorus and the gall bladder) and shoulder pains, followed by nausea and vomiting. There were jaundice and digestive disturbances, muscular rigidity and bile pigment present in the urine as shown by Baudouin's test, also by Loeffler's blue.

Operation.—When the abdomen was opened the gall bladder was found enlarged and adherent and drawn toward the median line of the body lying in immediate relationship with the pylorus. The gall bladder was opened in the usual way. Gallstones were found, and during the removal of these the scoop caught on a mass of what seemed at first to be a very stiff string of organized fibrin occupying the lumen of the organ. On removing this with artery forceps it was seen that the tough fibrin containing bile solids surrounded a stiff, pointed object which later was found to be an ordinary short sewing-needle.

How the needle came into the gall bladder is not known. It is presumed that the woman swallowed it, but this, of course, is only a hypothesis. The woman was accustomed to use needles like that found in her work and had occasionally put such objects into her mouth, as most women do, but does not remember having swallowed a needle. If the needle was swallowed it might easily have found its way into the gall bladder in the manner suggested above.

The body of the gall bladder is, as is well known, in relation by its under surface with the first portion of the duodenum, occasionally with the pyloric end of the stomach and the hepatic flexure of the colon. The needle might have traversed the wall of the intestinal canal proper in any one of these three portions and found the wall of the gall bladder in immediate apposition with the canal, which it had just left. It does not seem at all likely that the needle backed up stream, so to speak through the ampulla of Vater, the common and the cystic ducts. To any one familiar with the causation of gallstones, the probable relationship of the presence of the needle to the stones will be clear. It is quite fair to assume that such a foreign body as the needle, having carried in infection, could provoke sufficient inflammation of the gall bladder and ducts with consequent obstruction as to lead to precipitation of the bile salts and gallstone disease. There were no stones in the ducts and the symptoms, as might be expected, have quite disappeared.

331 North Delaware Street.

The Lachrymal Glands at Various Ages.—A. Goz (Inaug. Diss., Tübingen, 1908), has made an exhaustive study of the human lachrymal glands in male and female of various ages. The tissues were fixed in concentrated sublimate or in formalin; paraffin sections stained in iron hematoxylin and Delafield's hematoxylin and benzopurpurin B. Age bears a direct relation to the size and structure of the glands. The largest were found in women of about middle age. The size of the glandular epithelium decreases after the first year, producing a widening of the glandular lumen. In advanced age there is an increase of connective tissue and an invasion of the glandular substance. It is not uncommon to find in the aged the glandular tissue thus split up into a number of islets but normally glandular degeneration from this source does not occur. The lachrymal glands of the female have a larger average size and weight than those of the male.

REMOVAL OF AN EMBOLUS FROM THE COMMON ILIAC ARTERY, WITH RE-ESTABLISHMENT OF CIRCULATION IN THE FEMORAL

JOHN B. MURPHY, M.D.

CHICAGO

Patient.—Mrs. H. S., aged 41, was admitted to Mercy Hospital at 1:40 p. m., April 29, 1909.

Family History.—Father alive, well, aged 77; mother died at 42 of pulmonary tuberculosis.

Personal History.—The patient was born in Germany and came to Chicago twenty-five years ago; married at the age of 26; habits good; used no alcoholic liquors. Menstruation began at 14 and was until one year previous of the regular twenty-eight-day type; lasted four days; quantity moderate. In the last year the patient had had seventeen periods; flow scanty; last menstruation March 8, 1909; diminished in quantity. She had one child 9 years old; forceps delivery; was confined to bed five weeks; had cholecystic infection in the puerperium and was jaundiced for three months.

Previous Illness.—The patient always had good health up to about five years before the present illness, at which time she had acute rheumatism which lasted four weeks; she had a second attack two years later. The patient was not confined to bed in either of the illnesses and did not know that the endocardium or valves were involved. Following this attack she had shortness of breath and consulted a physician who said she had heart trouble.

Present Illness.—On April 25, 1909, the patient was seized with a sharp pain in the lower part of the left side of the chest and upper abdomen, which later extended down to the pelvis. It was considered pleuritis and the patient was given opiates. The pain continued in the lower part of the abdomen after that in the upper part had entirely disappeared, which would rather controvert the idea of a splenic infarct. On April 26, between 9 and 11 a. m., the patient became nauseated and vomited five or six times; did not have a chill and did not believe she had an elevation of temperature. One hour later both the left and right legs began to pain. A physician was called, and he gave a hypodermic injection in the left leg in the region of the pain. Both legs became cold and remained so until the following morning, when the pain in the right leg ceased and it regained its normal temperature. The left leg remained cold, was blue in the thigh and very pale and shriveled in the toes, foot and ankle. It was cold to midway between Poupart's ligament and the patella. There were large blue blebs scattered over the middle third of the thigh.

Examination.—At the time of admission to the hospital the pulse was 82, respiration 26, temperature not recorded. After the operation pulse was 76, temperature 98, respiration 26. At 4 p. m., April 30, pulse 84, temperature 98.6, respiration 28. May 1, at 4 p. m., pulse 82, temperature 99.2, respiration 26. A careful examination on admission showed that the patient had a mitral, direct and regurgitant murmur. Examination of blood showed 15,400 leucocytes; hemoglobin, 85 per cent. There was no pulsation in her left femoral artery. The upper margin of the area of demarcation that appeared then was about four inches below Poupart's ligament. The limb was undergoing dry gangrene, due to ischemia from arterial obstruction. The patient was immediately taken to the operating room and it was decided to remove the embolus that was occluding the iliac artery.

Operation.—(2:30 p. m., April 29.) The patient was placed on the table with the hip slightly elevated. Nitrous oxid was given for thirty seconds, while an incision four inches long was made downward from an inch above Poupart's ligament parallel to the femoral artery. It extended through the skin and connective tissue. The anesthesia was then stopped, the dissection continued and the femoral artery was exposed for a distance of 2½ inches. It was edematous, easily freed from neighboring structures and two provisional catgut ligatures were thrown around it with an aneurism needle but were not tied. These were used

preference to the Crile clamp so as to aid in elevating the artery, which was then incised for one inch parallel to its long axis. It was completely thrombosed. With a delicate forceps the clot (a bifurcated plug an inch and a half long) was drawn from below upward, when fresh arterial blood came from below, evidently collateral, through the femoral profundus. A finger was then placed on the lower end of the vessel inside the ligature loop, as shown in the illustration, so as to compress it and stop the return blood and still not injure the intima. With a delicate forceps I began extracting the clot from the proximal side; the artery did not empty. A delicate spoon was then introduced and more clot withdrawn, but no arterial blood came. Then a No. 6 soft catheter was introduced; it passed up a distance of seven and a half inches and was withdrawn filled with grumous, bloody debris, but no arterial blood followed. It was reintroduced but could not be forced through

Location of the clot and direction taken by the sound shown semi schematically.

a resistant body at that point. An ureteral catheter was then inserted; it met resistance at the same distance as before, but was forced through the thrombus and passed up nineteen inches, thus catheterizing the abdominal aorta. A small quantity of arterial blood followed its withdrawal. A uterine sound was then introduced. At a distance of seven and one-half inches it met resistance. It was forced a half inch farther, and on its withdrawal a large quantity of grumous, thrombotic debris came, but no arterial blood. It was pushed a little farther on and met a firm resistance. No blood followed its withdrawal. It was introduced for a third time, and with a little additional force at eight and one-half inches it seemed to pass through into a free space. This was followed by an intense arterial flow, carrying with it a lot of

embolic debris and fresh, bright blood. The arterial flow had then all the pressure and quantity of a normal femoral artery. The finger was then inserted in the ligature loop on the proximal side to stop the bleeding. With a fine silk suture on a full curved conjunctival needle a rapid continuous suture of the linear incision in the artery was made. On removing the digital pressure it oozed a little between the second and third stitches. Two additional supporting stitches at this point completely controlled the hemorrhage, and pulsation could be felt throughout the vessel. Unfortunately this operation was four days after the embolus was arrested in the common iliac just below the bifurcation of the aorta. The skin was necrotic and the limb cold to eight inches above the knee.

Postoperative History.—After the patient was removed to her bed she complained of pain and burning in her toes and ankle, the first sensation she had had in any of those parts since the onset. Considering the ease with which this clot was removed from the second inch of the common iliac artery, it is very much to be regretted that operation was not performed early in this case and in all of these cases. The operation was done without an anesthetic practically, and can be done painlessly with a little cocaine or salt solution injected into the skin. The collateral circulation was evidently making a great effort to establish itself, for as soon as I removed the plug from the junction of the deep and superficial femorals in the lower portion of Scarpa's triangle, the blood returned from the distal side. The suture of an incision in an artery is as simple as the suture of an intestine, if a sufficiently small needle be used. This I demonstrated in 1896, at which time I made the first successful end-to-end union of an artery that had ever been made, excising half an inch of the femoral artery at about the same point where I incised it to-day. At the line of demarcation the circulation was improved immediately after the re-establishment of the flow, becoming well marked a considerable distance lower; the amputation was made four days later four inches below the line of bleb formation that existed at the time the embolus was removed, and the flap survived. The circulation in all the smaller vessels at the line of amputation was fairly well established, but the trunk of the femoral was occluded by a loose, non-adherent clot, showing that it was the result of the suppression of the circulation from below or backing up of the blood which caused the thrombus, and not an inflammatory condition.

In cases of aseptic embolism immediate removal by division of the artery at the line of the embolism or below it should be resorted to. These emboli produce mere mechanical obstruction and the circulation is at once re-established by their removal.

The symptoms which indicate the occlusion of a large artery are, first, pain; second, ischemia of the limb; third, cooling of the surface; fourth, absence of pulsation in the arterial trunk. The number of hours that may elapse before a tissue becomes incapable of restoration has not been definitely determined, but from the length of time a constrictor may be kept on a limb for the suppression of hemorrhage and the vitality of the limb restored, we know that many hours of complete suppression of the circulation is not incompatible with restoration of the life of the tissues.

Since 1896 I have had two additional end-to-end sutures of arteries, one of the femoral in Scarpa's triangle for a bullet wound, and another of the first portion of the axillary just below the clavicle. In both end-to-end union was effected by my suture method and the circulation in the extremity promptly restored. A little over five years later all three of these end-to-end unions were examined by Dr. Neff and the circulation in the extremities was found perfect. I have also had a lateral suture of the external iliac and axillary arteries with good results. In September, 1908, a successful end-to-end anastomosis was made of the femoral artery into the femoral vein for endarteritis obliterans.

Since I published my original experiments and results in this line and demonstrated the feasibility of this work, Payr, Hoeffner, Eyner, Ullman, Carrel, Guthrie and others have supported the practicability of arterial suture and demonstrated that extremities and organs can be transplanted and the circulation maintained, if accurate suture of the arterial and venous trunks is made. The transplantation of organs must adapt itself best to embryologic ectodermic and endodermic glands, as their function is essentially a cellular one and not materially dependent on nerve supply, just as in horticulture the product of the graft depends on the "epithelial" cells in the bud, and these are maintained through nutrition derived from the engrafted trunk, the "epithelial" cell producing its normal or physiologic product.

In the removal of septic infarcts there is little to be gained in a practical way, as they are usually multiple. With the infarcts resulting from acute or chronic vegetations on the cardiac valves, good results should be obtained. Even cerebral ischemia should be amenable to this treatment, when due to an embolus arrested in the common or internal carotid by opening the common carotid and aspirating through a catheter; or a subclavian clot by incision of the axillary artery.

I believe that aspiration through a catheter is a better means of removing the plug than the one which I adopted. If the catheter is divided on the slant with its end open it can be readily introduced into the artery; unless the embolus is extremely hard it can with suction be drawn into or fragmented by the catheter and thus the artery freed.

Incision into the artery at the seat of arrest of the embolus, if it has been there for any length of time, is not an advisable procedure, as I found in my experiments that when a thrombus rested any considerable time on the intima it roughened it and increased its tendency to subsequent thrombosis. Therefore, the artery had better be divided above or below (preferably the latter) the point of impaction of the embolus. A gradual occlusion of the circulation does not produce gangrene in the extremity. In the British Museum are specimens showing that in gradual occlusion of the thoracic and abdominal aorta by cicatricial masses an abundant collateral circulation was developed sufficient to compensate for the occluded artery. It is the sudden ischemia that causes the gangrene.

The curved needle of the conjunctival type, which has its cutting edge easily rubbed off on a whetstone, is a good type of needle for deep work. A straight needle is difficult of insertion, and an "extremely fine needle" is not a *sine qua non* to arterial suture. After the removal of the Crile clamp or the digital compression there is often considerable oozing through the stitch holes. A gauze compression for thirty or forty seconds will completely stop all this bleeding. Silk should be used and not animal suture, as a clot rapidly forms around the silk, plugging the stitch hole.

The diagnosis of embolism of the mesenteric artery has never been made early enough to have this procedure available as a life-saving measure, but let us hope. Here, as in other types of emergency surgery, the operation must be timely in order to be successful. This applies particularly to the cerebral ischemias. The removal of an embolus from the pulmonary artery by Trendelenburg, while it terminated fatally, deserves special mention.

100 State Street.

Clinical Notes

FAVUS TREATED BY BACTERIAL INOCULATIONS

PRELIMINARY REPORT OF A CASE

G. A. PERSSON, M.D.
MOUNT CLEMENS, MICH.

This case of tinia favosa is perhaps particularly interesting, because, so far as my knowledge goes, there is no case of favus on record in which the opsonic treatment has been used.

Patient.—When the patient first came to my office, which was about Oct. 3, 1908, he presented a classical picture of the disease. The eruption, which is shown in Figures 1 and 2, was very extensive. The lower extremities were affected in the same proportions, particularly below the knees. The nails on both fingers and toes were also involved, which gave the patient continual annoyance. The characteristic "mouse" odor was evident. The patient's general condition appeared about normal. For twenty-three years he had suffered continually without any relief, except for very short periods of slight improvements during the first three years of the disease.

Fig 1.—Patient with tinia favosa, from photograph taken before beginning of treatment.

Examination.—Microscopic examination of the scales revealed the presence of the *Achorion schonleini*. It was decided to isolate the specific fungus of this disease and prepare a bacterial vaccine from it. A culture from the scales planted on agar and grown in the incubator for seventy-two hours gave the characteristic culture, microscopic examination of which revealed a mixed culture of the *Achorion schonleini* and *Staphylococcus aureus*.

A CORNEAL CURETTE

JOHN M. WHEELER, M.D.

NEW YORK

The instrument shown in the accompanying illustration may be used for curetting the cornea in any condition in which curetting is indicated, but its chief field of usefulness is in the removal of foreign bodies. Both edges are ground sharp, and the end of the instrument is ground to a point which projects a little beyond the shank. The construction of the curette is such that in its use the field of operation is not hidden from the surgeon. Most foreign bodies can be removed from the cornea without difficulty with the cutting edge of the instrument, and the foreign bodies almost invariably

stay on the curette. Occasionally a small bit of emery or like material penetrates the cornea to such a depth that the use of a sharp-pointed instrument is indicated. For this reason a point is supplied on the curette, and in using this point the shank of the instrument acts as a guard, so that there is no danger of perforating the cornea in removing foreign particles.

On account of its safety this little instrument will appeal especially to the general practitioner who of necessity must often remove foreign bodies from the eye.

64 West Fortieth Street.

Therapeutics

CHRONIC BRONCHITIS

Forchheimer, of Cincinnati, thoroughly discusses this troublesome disease in the *American Journal of the Medical Sciences*, February, 1909. He believes that the patient who has marked exacerbations in cold weather or has a prolonged winter cough should, if possible, go to a warmer climate during the cold season. This is especially advisable in cases in which there is an intermittence of the bronchial catarrh during the warm seasons, because many times chronic bronchitis begins as a recurrent winter cough which persists, until finally, it becomes an all-the-year cough. Like all recurrent inflammations and neuroses, the more frequently it occurs or the longer that it has lasted, the more persistent is the condition, consequently, every effort should be made to prevent a prolonged winter cough.

Of course, the most frequent cause of such a recurrent cough is latent or more or less active tuberculosis, but chronic bronchitis without tuberculosis while not of common, is certainly not of infrequent occurrence. If there is any season of the year that is worse for such patients than any other, it is the windy, dusty period of early spring, when there is but little, if any snow in the Northern and Eastern United States, and when it is a little too cold to sprinkle the streets properly, or the city authorities are careless in not beginning the sprinkling of the streets early in the season. Dust is certainly an exciting cause of the bronchitis, and also such dust carries with it germs which easily produce

infection, when deposited on mucous membranes that are so unhealthy as are the bronchial mucous membranes of these patients. Also, most of these patients become more or less debilitated by the cough and expectoration, and are susceptible to other infections, especially of the upper air passages.

It is too often forgotten in the treatment of chronic bronchitis that though the cough and expectoration is the most important symptoms and the one for which the patient desires treatment, a careful investigation into his general condition, and treatment aimed at his general health will cause more improvement than the administration of expectorants, either sedative or stimulant. Generally, however, some expectorant may be advisable. In this form of bronchitis, opium, or any of its derivatives, is rarely indicated as a sedative, as the cough is usually for the purpose of removing the secretion in the bronchial tubes, and a sedative, or anything that would diminish the irritability of the nerves so that the secretion would accumulate and not be expectorated, would be inadvisable and contraindicated. Also, ipecac, alkalies, and pilocarpin, mentioned by Forchheimer, are rarely indicated in chronic bronchitis. Ammonium chlorid for its stimulant action in causing the mucous membrane to secrete a healthy mucus may for a short time be of advantage, but should not be used too long, as it sooner or later causes nausea and disturbance of the stomach.

In certain cases, some of the aromatic expectorants as turpentine, benzoates, eucalyptol, and santal oil may be of benefit to the patient. Creosote or some of its many preparations may be of value, but most of these drugs, if administered for any length of time, cause indigestion, and, if there is any kidney disability, many of them are contraindicated.

Terpin hydrate is often the best and simplest drug to administer.

If an asthmatic condition be present with the bronchitis, potassium or sodium iodid becomes the best treatment.

Circulatory debility should certainly be treated. Strychnin alone will often do these patients good. Arsenic in small doses is sometimes of advantage.

Forchheimer believes that there is no doubt that some of the aromatic oils, when inhaled from proper inhalers, are of great value.

He also calls attention to the posture treatment when profuse bronchial secretion tends to remain in the bronchial tubes, and would gradually raise, little by little, the foot of the bed of such a patient, until the head is distinctly lower than the feet. He finds by experience that the first elevation of the bed at the bottom should be about two inches; later this may be increased to four or five inches. If there is one particular part of the lung where the secretion accumulates such a side posture as will facilitate the flow of this secretion toward the larger tubes and thus promote expectoration, may be adjusted by pillows or bolsters.

In fetid bronchitis, creosote, thymol, oil of eucalytus, or oil of pine inhalations are of benefit. Also the administration of creosote and of santal oil internally seems to be of benefit, but the more thoroughly the dilated bronchi are evacuated of their secretions by posture, the less odor will the expectoration have. Also, such patients with fetid bronchitis should, if possible, sojourn for some time in pine woods.

It should not be forgotten that these patients in some instances have combined with the necessary cough an entirely unnecessary one, a cough that raises nothing and is due to throat irritations, often to an enlarged and irritated lingual tonsil. Such a cough can be more or less controlled by the patient, if he is told that it is almost unnecessary, and may also be markedly helped by a few daily local applications of boroglycerid to the lingual tonsil. Soothing alkaline gargles will relieve this kind of a cough, which should not be treated by sweet, irritating, or nauseating expectorants.

Forchheimer well says that the best climate, or the best "cure," to which the bronchitis patient should be sent is determined by the individual condition of that patient. While one patient had best go to New Mexico, another had best take a sea voyage; while one needs circulatory and skin stimulation at some sanatorium or hot springs, another needs exercise and mountain climbing.

As Forchheimer suggests, and as has been pointed out by others, there can be no question that we do not frequently enough teach these bronchitis patients respiratory exercises.

Patients with some arteriosclerosis do well on small doses of iodid, given for long time. Other patients need sufficient daily exercise to cause profuse perspiration.

EPILEPSY

Lest too much reliance be placed on the administration of drugs in this disease, it is well for us to consider the statements made by Dr. William T. Shanahan, assistant physician at the Craig Colony for Epileptics, Sonyea, N. Y. (*The Dietetic and Hygienic Gazette*, March, 1909). He says that the three great essentials in the management of epilepsy are the diet, hygiene, and occupation, and that it is only after these have been arranged to the best possible advantage of the patient that medicinal treatment is to be considered.

To ascertain the best diet for the individual epileptic, the gastric and intestinal digestive powers should be thoroughly investigated, and to do this properly, the twenty-four hours' urine and the feces should be carefully examined. Such examinations, at least if several times done, will disclose many errors in metabolism, which may be prevented by treatment, management, or a radical change in the diet. The digestive system being made as perfect as possible, the toxins that so often are the instigators of epileptic attacks will not form, be absorbed, and circulate in the blood. Not only should the kidneys and intestines be made as nearly as possible perfect excretory organs, but the skin should be made as active as possible by massage and exercise.

Of course all epileptics should avoid alcohol, and often tea and coffee. Rich, greasy, highly seasoned foods, or indiscretions as to amount, should not be allowed to occur in the dietary of an epileptic, and special care should be exercised that the epileptic receives nothing but the freshest and most properly cooked food.

If, in spite of corrections in the diet, intestinal fermentation and putrefaction occur, the various culture preparations of lactic microbes may be administered, or yeast often acts to advantage in preventing such intestinal conditions. Radical changes in diet—from a mixed diet to a vegetable diet, or to a milk diet, or to a temporary buttermilk diet—may aid in eradicating the disturbance in the intestine.

Constipation should certainly never be allowed in epileptics, and drugs may be administered to prevent it, if must be, although of course it is best to prevent constipation by diet, exercise, and by drinking plenty of water. The best laxative, if one must be given, must be determined by the individual patient. If, in spite of ordinary laxative drugs or laxative treatments, the feces tend to remain long in the intestines, active catharsis with calomel or castor oil must be caused periodically. With such persistent constipation the advantage of the administration of sweet oil, and of the high injection into the colon of warmed sweet oil should be remembered.

Shanahan says that for the control of the epileptic seizures, bromin or its salts still hold an important place. He does not state which bromid he prefers, but sodium and potassium are probably the best. If plenty of water is drunk to make the skin and kidneys active, if the bowels move well daily, and if the skin is properly bathed, and good, healthy out-door exercise is taken, the disturbing symptoms of bromism will not develop, especially as the large doses once given have been found unnecessary. If salt (sodium chlorid) is more or less thoroughly removed from the diet, it has been found that the bromin salt, perhaps preferably sodium bromid, takes its place, and less bromid is needed to control the frequency of the epileptic seizures. Shanahan cautions not to stop suddenly the administration of large doses of bromids.

He also states that if the excretory organs of the patient are kept active, the condition of status epilepticus, or rapidly repeated seizures of epilepsy, will not occur; hence the prophylactic treatment is the best. Such a condition, however, being present, he says that chloral hydrate must be used: it is best given by enema and its retention may be aided by laudanum. He does not say how much is generally needed, but states that it should be used with caution, and exhaustion guarded against by the use of stimulants such as aromatic spirits of ammonia, and enemata of strong black coffee, at a temperature of from 100 to 105 F. If needed, he would also give physiologic saline solution intravenously or by hypodermoclysis, and if there is much cardiac depression he uses strychnin, digitalis, and strophanthus.

At the onset of the status epilepticus, gastric and intestinal lavage are often of value. Venesection may be used in plethoric cases, and lumbar puncture has been tried, but with only questionable success. If the epileptic seizures are rapid and severe, chloroform inhalations may be administered until the chloral has had time to absorb from the rectal or colon injection.

Of course in treating any individual epileptic, an attempt should be made to correct any physical disability that may be present. Adenoids and enlarged tonsils should be removed; decayed teeth should be cared for; eyes should be fitted with glasses, if they require it; hemorrhoids should be removed, if present; pelvic disturbances in females must be prevented, medicinally, if may be, or operatively if must be.

Shanahan does not speak of the disturbances of menstruation being a frequent cause of epilepsy in girls and women, nor of the advantage of the administration of thyroid both as an emmenagogue and as a preventive of nitrogen poisoning. It is a fact that many female epileptics may be greatly improved and even cured with general management and the proper administration of thyroid.

SATURDAY, MAY 22, 1909

AORTITIS, AORTIC ENDOCARDITIS AND SYPHILIS

With the development of two new diagnostic criteria of syphilis, the Wassermann reaction and the finding of spirochetes, it has been possible to approach the so-called parasyphilitic diseases from a new ground, with the result of brilliantly confirming the conclusions previously reached by clinical observation. As the parasyphilitic affections are late manifestations or results of syphilitic infection, and for the most part not accompanied by definite syphilitic lesions, the search for spirochetes has not been of much help in their etiologic determination, since these organisms are usually found with difficulty in even the most typical lesions of the tertiary stage. With the help of the Wassermann reaction, however, it has been demonstrated that the relationship between syphilis and such diseases as tabes and general paralysis is fully as frequent as the clinicians have long believed, and if anything more so. The variations in the results obtained by the laboratory investigators who have applied the serum test to these diseases, are about the same as we have been accustomed to see reported by clinicians who were endeavoring to establish a relationship on the basis of clinical history and coexisting syphilitic manifestations.

Among the parasyphilitic lesions degenerative and productive changes in the aorta, with resulting aneurism or aortic insufficiency, have long presented problems to the pathologist and clinician of great practical as well as theoretic interest. Even Ambroise Paré, Morgagni and other early masters of medicine recognized that syphilis played an important rôle in the etiology of arterial diseases, but we owe especially to the work done under Heller at Kiel our present understanding of the characteristic features of aortic syphilis. Now it is generally recognized that fleshy nodular thickenings of the aorta, most abundant in the ascending part, and frequently extending to the aortic valves with resulting incompetence, are commonly of syphilitic origin, especially when they concern individuals in the prime of life. Microscopically, these lesions are found to involve chiefly the media and adventitia, consisting of foci of round cells in the vicinity of the vasa vasorum, while in the media may be found foci of necrosis which sometimes are typically gummatous in character. As a rule, the histologic features of these lesions are not such as to prove

conclusively their syphilitic origin, and consequently the pathologists have discussed at much length the proportion of such aortic lesions that should be ascribed to syphilis, and the possibility of similar lesions being produced by the acute infectious diseases. It seems to be generally accepted, however, that the most usual cause of such changes in the aorta is syphilis, although it is possible and probable that they are not by any means specific evidence of syphilitic infection. In other words, their status is just about the same as that of tabes and paresis in respect to etiology. Mönckeberg found that of the reported cases of aortitis 33 per cent. showed positive evidences of syphilis, while in a further 44 per cent. other parasyphilitic affections coexisted. Chiari reported that of 27 cases of undoubted syphilis examined post-mortem aortitis was present in 16, and of 44 paralytics 21 showed aortitis, indicating that more than one-half of all syphilitics coming to autopsy show characteristic lesions in the aorta. Similar results have been obtained by clinical observation. In v. Strümpell's clinic of 24 cases, tabes and aortic lesions, chiefly aortic insufficiency, coexisted in 15.

For some reason the application of the serum test to aortic disease has lagged behind its use in the study of nervous cases, but the results that have now been obtained are fully as convincing, and perhaps even more valuable from the therapeutic point of view than the results in tabes and paralysis. Fränkel and Much first applied the Wassermann test to the blood from cadavers showing aortitis with aortic insufficiency, and in all the six cases examined the reaction was positive. Citron¹ has studied systematically, by the serologic method, with interesting results, all the cases of aortic insufficiency coming to Kraus' clinic in Berlin in the past year and a half. Although only 14 per cent. of all cases of uncomplicated aortic insufficiency gave definite, and a further 26 per cent. suggestive, clinical evidence of syphilis, yet no less than 62.6 per cent. gave a positive serum reaction.

The earlier attempts to locate spirochetes in the aortic lesions resulted for the most part negatively, so that the positive findings reported by Schmorl, Reuter and Benda were accepted with more or less skepticism in view of the possibilities for error that the degenerated aortic tissues offer to the searcher for spirochetes. However, now that Wright and Richardson² have reported the finding of structures morphologically identical with *Spirochæta pallida* in all of five cases of aortitis examined by them, there will be no hesitation in the acceptance of these positive findings by Americans who are familiar with the splendid technic of the Boston laboratory.

All the above findings taken together would seem to prove finally the importance of syphilis in the etiology of the nodular form of aortitis which is so frequently

1. Berl. klin. Wehnschr., 1908, xlv, 2142.
2. Boston Med. and Surg. Jour., 1909, clx, 529.

associated with insufficiency of the aortic valves. Indeed there seem to be relatively few cases of simple aortic insufficiency that are not due to syphilis, especially if we exclude those cases where there is a history of rheumatism. As the Wassermann test seems to have distinct value in indicating the activity of syphilitic lesions, there would seem to be an excellent opportunity for therapeutic advance in the treatment of aortic regurgitation when of syphilitic origin, as most of the uncomplicated cases are shown to be.

RELATION OF HUMAN AND BOVINE TUBERCULOSIS

We are approaching the end of the solution of a problem which for many years has been the subject of bitter controversy and during the past eighteen years has been the object of perhaps more extensive work than any other in medicine. The relation of human and bovine tuberculosis is a question of first importance and deserving the most careful consideration.

The investigations which have led up to the proof of the intercommunicability of the disease in man and cattle may be divided into three periods: first, those taking place before the publication, in 1882, of the discovery of the tubercle bacillus by Koch; second, those occurring between the time of the discovery of the tubercle bacillus and its differentiation into human and bovine types by Theobald Smith in 1896-1898; third, those occurring since the establishment of these two types.

During the first period, it was shown by direct experiment that cattle could, though with difficulty, be infected with tuberculous material of human origin; their resistance to the human virus is so great, however, that it is unlikely that the infection occurs naturally.

Evidence of infection from tuberculous cattle to man could not, of course, be sought experimentally, but numerous observers collected statistics which furnish much circumstantial evidence that not infrequently man is infected with the virus of bovine tuberculosis. Numerous cases were studied in which, among children especially, the disease was in all probability caused by consumption of milk from tuberculous cows. A smaller number of cases, but cases furnishing more conclusive proof, were those in which direct inoculation occurred, as in those cases where tuberculous lesions followed wounds received by veterinarians and butchers while handling tuberculous meat.

The evidence obtained during the second period, that is, after the discovery of the tubercle bacillus, differed but little from the preceding, except that the demonstration of the bacilli made the diagnosis more certain, and its cultivation in pure culture gave a greater value to the direct inoculation experiments in animals. This circumstantial evidence was so convincing that it would doubtless have served to bring about the observance of adequate precautionary measures had it not been for the spirit of controversy which existed.

The discovery of the two types of tubercle bacilli, human and bovine, made possible the solution of the problem. On the basis of this distinction the German commission, the British commission and a number of individuals have proved that bovine tuberculosis is communicable to man. In over 300 cases reported in the literature in which the determination of the variety of bacillus present has been made, bacilli of the bovine type have been found in over 60 cases, a little more than 20 per cent. This can not be taken as representing the true incidence of bovine infection in man, since in some of the series investigated cases were chosen in which it seemed especially probable that the infection was of bovine origin. The results indicate clearly, however, that bovine tuberculosis is a source of danger to man sufficiently great to demand rigorous precautionary measures against it.

To arrive at a more accurate knowledge of the incidence of infection with the bovine type of bacillus in man, a great number of cases of tuberculosis, including the various forms of the disease, must be brought under investigation.

It will be of great interest and importance to see if certain forms of tuberculosis are constantly associated with one or the other type of bacillus. It is already evident that the bovine bacillus rarely, if ever, produces pulmonary tuberculosis. On the other hand, it has been found in a considerable number of cases of cervical adenitis and *tabes mesenterica*, as well as in other forms of tuberculosis.

The bearing which the type of bacillus present in a given infection will have on the therapeutic treatment of the case is not yet clear. In most of the work which has been done on the immunization of cattle against tuberculosis, living but attenuated cultures of tubercle bacilli of the human type have been used; there have been a few experiments, however, which indicate that vaccinations with attenuated cultures of bovine bacilli are more potent to protect cattle than are the vaccinations with the human bacilli. This fact may become significant in the treatment of human tuberculosis. Although at present there is but little to indicate that tuberculins prepared from the two types of the bacilli differ essentially, yet individuals with tuberculosis who had received one kind of tuberculin over a long period of time without evident benefit sometimes show a definite and progressive improvement when a change is made to tuberculin produced by the other type of bacillus.

Whether this result depends on the type of bacillus present in the infection has not been investigated, nor have we enough evidence to say whether we should use the homologous tuberculin or vaccine or the heterologous ones, but in the present unsatisfactory state of the therapy in tuberculosis, advantage should be taken of these points if any advantage lies in them. Further investigations are required along these lines.

fessor of medical jurisprudence. The faculty then met and elected the following officers: Dr. Montague J. Lowry, president; Dr. T. Alexander Barber, dean; Dr. Nathan L. Clark, vice-president, and Dr. John R. Tackett, treasurer.

NEW JERSEY

State Society to Meet.—The Medical Society of New Jersey will hold its annual meeting at Cape May, June 23-25.

Society Meetings.—At the annual meeting of Mercer County Medical Society, held in Trenton, May 11, the following officers were elected: President, Dr. Charles H. Mitchell; vice-president, Dr. Gustave A. Schoening; secretary, Dr. Edgar L. West; treasurer, Dr. Iranaeus M. Shepherd; recorder, Dr. Charles J. Craythorn, and delegates to the state medical society, Drs. William S. Lator, George N. J. Sommers, and Paul L. Cort, all of Trenton.—Salem County Medical Society, at its annual meeting, held in Salem, May 5, elected the following officers: President, Dr. John M. Summerill, Penn Grove; vice-president, Dr. George W. Fitch, Daretown; secretary-treasurer, Dr. Henry Chavanne, Salem; reporter, Dr. John F. Smith, Salem; censors, Drs. William H. James, Pennsville, Frank B. Harris, Canton, and Richard M. Davis, Salem, and delegates to the state medical society, Eugene E. DeGroot, Woodstown, and Lester H. Hummel, Salem.

NEW YORK

Site for Insane Hospital Again Opposed.—It is announced that the State Commission in Lunacy had chosen a new site for the proposed asylum at Farmington, L. I. With the announcement that an offer for property had been accepted, the same opposition that was raised in connection with the Grenvale purchase is met. The citizens of Farmington in a mass meeting filed a protest with the governor, the senator, assemblymen, and lunacy commission, against the location of a hospital for the insane at or near the village.

Bills Signed.—Governor Hughes has signed the following bills: Senator Platt's, providing that any person knowingly bringing a domestic animal suffering from an infectious or contagious disease into the state shall be liable to all damages caused by the spreading of such disease; Senator Raines', relative to quarantine for rabies, posting notices and providing a penalty for destroying such notices while they are in force; Representative Shea's, providing that the state shall pay 50 per cent. of the appraised value of an animal condemned for glanders; Representative Boshart's, giving the chief veterinarian of the State Department of Agriculture the same authority to quarantine on account of contagious diseases, as is now held by the assistant commissioners, and also providing for a more stringent labeling of articles termed in the agricultural law "concentrated commercial feeding stuffs," and Senator Newcomb's, rearranging the control of infectious and contagious disease hospitals in New York City as between the various city departments devoted to this work.

New York City

New Training School Opened.—The formal opening exercises of the New Bellevue Training School for Nurses were held April 28. The building is located between East Twenty-fifth and Twenty-sixth streets, and cost about \$1,000,000.

Hospital Suspends.—The Brooklyn Memorial Hospital for Women and Children has been closed because the work of the institution has been so seriously handicapped by the lack of facilities. Arrangements are being made for the erection of a new structure which it is hoped may be erected in two years. The Memorial Dispensary which has been connected with the hospital has been removed to Sterling Place.

To Help the Blind.—The New York Association for the Blind recently gave a benefit at the Hippodrome where between five and six thousand dollars was raised. In connection with the entertainment was an exhibition demonstrating the various kinds of work that could be done by the blind. The association asks \$100,000 as a permanent fund to carry on its work and already has \$85,000 pledged on condition that the remaining \$15,000 be raised.

Enlarge City Hospital.—Plans have been filed for the erection of a two-story and attic pathologic laboratory building as an annex to the Metropolitan Hospital, Blackwell's Island. The main floor will contain the offices, the museum and specimen room and a room for autopsies; the second floor will be fitted as a library and with laboratories for microscopical, chemical and bacteriological research, and also a special private laboratory for the surgeons and the attic will be fitted as a menagerie for animals for experimental use. The structure will cost \$40,000.

United Hebrew Charities May Get Million.—The \$1,000,000 left to the United Hebrew Charities on condition that an agency should make collections for the six charities and that the funds should be distributed among them by Louis A. Heinsheimer, is still in the hands of Alfred M. Heinsheimer, as several of the institutions refused to accept the terms of the will. A meeting was recently held at which a thorough canvass of the situation was made and a resolution was passed calling for the appointment of a committee to consist of one person from each of the six institutions and each of these to choose three additional persons. The testator desired this plan of cooperation in order to reduce the expenses of collection.

NORTH DAKOTA

County Medical Society Organized.—The Richland County Medical Society was organized at Wahpeton May 3. Dr. Martin W. Ivers, Abercrombie, was elected president; Dr. Robert H. Devine, Wahpeton, vice-president; Dr. Timothy O'Brien, Wahpeton, secretary; Dr. Louis W. Meckstroth, Wahpeton, treasurer, and Dr. Charles P. Spottswood, Hankinson, censor.

State Association Meeting.—The annual meeting of the North Dakota Medical Association was held in Fargo, May 11 and 12. The following officers were elected: President, Dr. John E. Countryman, Grafton; vice-presidents, Drs. Henry H. Healy, Grand Forks; N. Oliver Ramstad, Bismarck, and Louis W. Meckstroth, Wahpeton; secretary, Dr. Hezekiah J. Rowe, Casselton (reelected); treasurer, Dr. J. Dempsey Taylor, Minot (reelected); delegate to the American Medical Association, Dr. Victor H. Stickney, Dickinson; alternate, Dr. Zella W. Stewart, Grand Forks, and councilors, Drs. P. J. Artz, Jamestown; Charles McLachlan, New Rockford; R. W. Pence, Minot, and Edgar A. Pray, Valley City. Grand Forks was chosen as meeting place for 1910.

OHIO

Will Not Prescribe Liquor.—The Wyandot County Medical Society, at its meeting April 29, adopted a resolution that its members refuse to furnish prescriptions for intoxicating liquors until, after having made a personal examination of each patient, it is deemed that the stimulant is necessary.

Sanatorium Dedicated.—On May 1, the Brookside Sanatorium, Dayton, was formally presented to the local tuberculosis society by E. B. Markey, who, in his address, dedicated the institution to the cause of bettering the condition of unfortunate consumptives. Rev. William A. Hale delivered an address on the "Great Cause of Tuberculosis." The sanatorium is located within six miles north of Dayton, and the buildings consist of a two-story brick house, and several structures erected on plans approved by the International Tuberculosis Congress.

Cincinnati

Fresh Air Society.—At the annual meeting of the Fresh Air Society it was announced that the society expected to care for from 2,000 to 3,000 on its farm near Terrace Park, during the coming season, and a plea was made for funds for this purpose, for the painting of cottages, fitting up the dining room, and constructing cement walks, for all of which \$1,100 is needed.

New Plans for Interne Examination.—A new plan for the examination of internes has been adopted in Cincinnati. Four hospitals consented to hold a single examination under the auspices of the staff of the Cincinnati Hospital, the successful candidates being allowed to select the hospital in which they prefer to serve, the selection to be made in order of rank. There were 23 who passed the examination, but as there were only 20 positions to fill, 3 will act as alternates.

PENNSYLVANIA

Personal.—Dr. and Mrs. William G. Miller, New Castle, will sail for Germany early in June.—Dr. Ernest L. Clark has been elected president of the Media Free Library Association.

Appropriations Cut.—Governor Stuart reduced in general the appropriations to the state and semi-state institutions recommended by the legislature. The appropriations to these institutions, however, are higher than they were two years ago.

Food Bill Approved.—Governor Stuart approved the Todd-Murphy Food Bill, May 13. The act is now in force, previous conflicting statutes being repealed thereby. This act permits the use of benzoate of soda and sulphur dioxide as preservatives. A long list of preservatives is forbidden by the act,

including boron compounds, pyroligneous acid, salicylic acid, formaldehyd, sulphate of copper, alum and many others.

Portrait of Dr. Agnew Unveiled.—On May 13, a portrait of the late Dr. D. Hayes Agnew was unveiled at Mercersburg Academy. The members of the Franklin County Historical Society and the medical societies of Mercersburg, Chambersburg and other towns in Franklin county attended the ceremony. The address was delivered by Dr. J. William White, professor of surgery in the University of Pennsylvania.

Tuberculosis Society Directors Elected.—At the annual meeting of the Pennsylvania Society for the Prevention of Tuberculosis, held in Philadelphia April 14, the following directors were elected: Drs. Howard S. Anders, Frank A. Craig, J. Clinton Foltz, Albert P. Francine, C. Lincoln Furbush, William D. Robinson, Jr., William C. White, T. Mellor Tyson, J. Willoughby Irwin, Henry D. Jump, and J. Gurney Taylor, Philadelphia, and Dr. Charles H. Miner, Wilkesbarre.

Bill Vetoed.—Governor Stuart has vetoed the Blewitt bill, which requires all state or other hospitals in the state receiving annual appropriations from the state to furnish to sick or injured firemen, either permanent or volunteer, caused by exposure or accident while in the performance of their duties, a private room or rooms, together with all medical attention, board and supplies, free of charge. The Governor said that there appears to be no occasion for such legislation, and that therefore the act is not approved.

Philadelphia

City to Give Milk to Babies.—The Department of Health and Charities is prepared to distribute free milk and ice to babies during the hot months of the summer. This is the first time that the city has undertaken to supply milk to the children of the poor.

Health Bureau Chief Resigns.—Dr. Alexander C. Abbott, chief of the bureau of health, has resigned his position to take effect June 1. He will devote his time to his work at the University of Pennsylvania and will have charge of the laboratory of hygiene and physiology.

Educational Tuberculosis Exhibition.—An educational tuberculosis exhibition by the Pennsylvania Society for the Prevention of Tuberculosis, was opened in the Auditorium of the Kensington Young Men's Christian Association, May 17, and will remain five days. Demonstrations are being given each day and preventive measures for combating the disease are being outlined.

Lectures to Mothers.—At a conference, May 13, between the Director of Public Health and Charities, and Mrs. Frederick Schoff, president of the Mothers' Congress, arrangements were made for a series of lectures to mothers on the care and treatment of infants. The lectures will be delivered in the public schoolhouses after school hours by the assistant medical inspectors and nurses connected with the health bureau.

WASHINGTON

First-Aid Equipment for Schools.—The Seattle board of education has ordered that first-aid cases, blankets and hot-water bottles be installed in all school buildings having domestic science departments. The cost of this equipment will be a little less than \$600.

Hospital Notes.—Work will soon commence on the hospital to be erected by the Sisters of Charity between Jefferson and James streets and Seventeenth and Eighteenth avenues, Seattle. The building will be of steel brick and concrete construction, six stories in height, and will cost about \$250,000.

—Physicians of Bremerton have raised \$1,100 by popular subscription to purchase a site for a hospital for Kitsap county. The building proposed will cost about \$7,000.—Plans for a three-story addition to the Hoquiam General Hospital to cost about \$10,000, have been prepared, and construction work will soon be begun.—The Emergency Hospital, Seattle, on the fourth floor of the new Municipal Building, was officially opened March 31, when 19 patients were transferred to the hospital. About \$125,000 has been spent on the new hospital, which is under the direction of Dr. James E. Crichton, commissioner of health, assisted by Drs. Frank S. Bourns and Inslee B. Greene.

WISCONSIN

Home for Consumptives.—Plans are being made in Milwaukee for the construction of an isolation hospital for consumptives at Wauwatosa, on a site purchased three years ago for \$32,000. The principal building on the ground will be remodeled to conform to the modern ideas of open-air treatment, and eventually smaller cottages will be erected for the use of patients.

Personal.—Dr. Adelbert Schneider, Milwaukee, has returned from Europe.—Dr. Lawrence P. Mayer, Hudson, is seriously ill with septic pneumonia.—Dr. A. D. McKinley has resigned as house surgeon at the Johnston Emergency Hospital, Milwaukee, to become superintendent of the Fox Lake Sanitarium.—Dr. James W. St. John, Janesville, has been appointed fire and police commissioner.

GENERAL NEWS AND COMMENT

Vanderbilt Alumni Meet.—The alumni of Vanderbilt University Medical Department, Nashville, Tenn., will have their headquarters at Young's Hotel at Atlantic City during the meeting of the American Medical Association, and on June 8 a banquet will be given at the hotel at 8 p. m.

Meeting of Milk Commissions.—The third annual meeting of the American Association of Medical Milk Commissions will be held June 7, at the St. Charles Hotel, Atlantic City. The association now has a membership of 48 milk commissions. Proceedings of the 1908 session will be mailed in a few days.

Internists Elect.—At the annual meeting of the Association of American Physicians, held in Washington May 11 and 12, the following officers were elected: Dr. Henry Hun, Albany, N. Y., president; Dr. Frederick Forchheimer, Cincinnati, vice-president; Dr. George M. Kober, Washington, secretary; Dr. Solomon Solis Cohen, Philadelphia, recording secretary; Dr. J. P. Crozer Griffith, Philadelphia, treasurer, and Dr. Henry Sewell, Denver, councilor.

Gastro-Enterological Meeting.—The twelfth annual meeting of the American Gastro-Enterological Association will be held at Atlantic City at the Hotel Windsor, June 7 and 8. The address of the president, Dr. Julius Friedenwald, Baltimore, will be on the "Development of Gastrology," and in the evening of the first day a symposium on "Gastro-Enterostomy," participated in by Drs. W. B. Cannon, Fred T. Murphy, and Franklin W. White, Boston, Henry W. Bettmann, Cincinnati, and John M. T. Finney, Baltimore.

Laryngologists to Meet.—The thirty-first annual congress of the American Laryngological Association will be held in Harvard Medical School, Boston, May 31 to June 2, under the presidency of Dr. Algernon Coolidge, Jr., Boston. The entertainment includes a luncheon given by the Boston members to the fellows and their ladies and the president's reception on the first day; a luncheon given by the Boston members of the American Otological Society and the American Laryngological Association to visiting fellows and the annual dinner on the second day. On the third day the Otological Society and Laryngological Association discuss nasal and pharyngeal conditions as causative factors in aural diseases.

The Carroll Fund.—The following subscriptions have been received since the last report:

From Medical Officers of the Army.....	\$ 20.00
Dr. F. W. Taylor, Paauilo, Hawaii.....	5.00
Medical Society, Sioux County, Iowa.....	11.00
Dr. A. de Bey, Orange City, Iowa.....	
Dr. G. A. F. de Lespinasse, Orange City.....	
Dr. C. de Jong, Orange City.....	
Dr. A. L. Druet, Boyden, Iowa.....	
Dr. N. G. O. Coad, Hull, Iowa.....	
Dr. D. J. Gleusteen, Alton, Iowa.....	
Dr. G. Harris, Hull, Iowa.....	
Dr. F. L. McAllister, Hawarden, Iowa.....	
Dr. C. S. McCarthy, Hawarden, Iowa.....	
Dr. H. D. Oggel, Maurice, Iowa.....	
Dr. D. J. Werkman, Secretary, Hull, Iowa.....	
Kansas State Medical Society, Columbus, Kansas.....	55.50
Dr. A. W. Hewlett, Ann Arbor, Mich.....	5.00
Dr. Alex. C. Soper, Jr., Chicago.....	5.00
Dr. J. H. Carstens, Detroit.....	5.00
Ohio State Medical Society, Columbus, Ohio.....	112.00
Denver County Medical Society, Denver.....	35.00
Physicians Round Table of the Chicago Athletic Club.....	20.00

	\$ 273.00
Previously acknowledged	3,825.65
Total	\$4,098.65

The sum of \$3,326.50 is still needed to raise the mortgage on this property. Remittances should be sent to Major Ireland, care Surgeon-General's Office, War Dept., Washington, D. C.

Tropical Medicine.—The Far Eastern Association of Tropical Medicine will meet in Manila, P. I., March 6-14, 1910. The session will open at Manila. On the second day protozoology and helminthology will be considered; on the third day, cholera, plague and leprosy; on the fourth day, surgery, obstetrics and diseases of children; on the fifth day, fever, in the tropics, including malaria, typhoid, etc.; on the sixth day, dysenteries and beriberi; on the seventh day, the association will go to Baguio, Benguet, the summer capital of the Philippines, where tuberculosis, climate, hygiene and sanitation will be discussed.

and the business session will be held. Dr. Paul C. Freer, Manila, president of the association, is anxious to have a number present from the United States in addition to the contingent from the far East, and suggests that any who are intending to make a tour of the world eastward, to so plan their routes as to arrive at Manila in March, the best season, thus having January and February, the best months in the year for India.

FOREIGN

Prizes Offered by the Spanish Academy of Medicine.—The Academy of Medicine at Madrid offers a prize of \$150 and a gold medal for the best works received on "Heart Failure" and "Infant Feeding." The works must be in Spanish, French or Latin, and be sent in anonymously before June 30, 1910. The secretary is D. M. Iglesias, Calle Mayor 6, Madrid, Spain. Among the other prizes offered are two for the best description of some epidemic in Spain which the writers have passed through, citing cases, treatment, etc., with a certificate signed by the *alcalde* or priest as to the writers' professional zeal and devotion during the epidemic. The Rubio prize of \$240 is to be awarded for the most important work or discovery by a Spanish physician during the preceding two years.

LONDON LETTER

(From Our Regular Correspondent)

LONDON, May 8, 1909.

Bequest for Surgeons Who Contract Blood Poisoning in Operating

Mr. George Smith, a dental surgeon of Newent, Gloucester, who died at the age of 77, made a novel bequest. He left the residue of his estate, valued at \$58,000, after payment of certain legacies to the Royal Infirmary, Manchester, and University College Hospital, London, in equal shares, to be used for the benefit of the members of the surgical or dental staff who may be disabled by infection from puncture or who may contract blood poisoning while examining or operating on patients or making postmortem examinations.

Bequest for a Hospital Free from Socialist and Religious Control

A surgeon, Mr. John Kershaw, F.R.C.S., of St. Anne's-on-Sea, Lancashire, has left \$250,000 for the erection and maintenance of a hospital on his Sunfield estate at Royton, a cotton district in Lancashire. The hospital is to be absolutely free to all who seek treatment. No inquiry is to be permitted as to the means or religious belief of the applicants and no minister of religion nor any socialist is to be an officer of the hospital.

Early Diagnosis of Cancer of the Uterus

At the 1907 annual meeting of the British Medical Association the Section of Obstetrics and Gynecology adopted a resolution requesting the council to appoint a committee to consider the best means of disseminating knowledge of the importance of the early recognition of cancer of the uterus. The committee presented a report which was considered and generally approved by the same section in 1908. At a meeting held on April 28 last the council approved of an appeal to doctors, midwives and nurses to promote the earlier recognition of uterine cancer and directed that this should be communicated to British and colonial medical and nursing journals. The appeal is a lengthy document in which the early diagnosis of the disease is minutely discussed. Its curability by operation in the early stage is emphasized. It is pointed out that the early symptoms are irregular bleeding of any description, even if only in traces—bleeding postcoitum and watery, blood-tinged discharge. There may be no loss of strength or other symptom.

Sir Almroth Wright on Immunization Against Disease

Sir Almroth Wright was entertained at a dinner given in his honor by the Authors' Club, where he delivered an address on "Immunization Against Disease," which was listened to with great interest by a distinguished audience. He contended that our civilization was by no means as complete as we were wont to think. We had not yet come to appreciate the rôle of bacteria, which were among the newly discovered things of the world. We thought we had conquered them by our sanitation, but we had only been fighting against a small portion of them. We had got the better of smallpox, typhoid and dysentery, which now killed very few people in England. But the most serious ills of life now produced by bacteria were not epidemic diseases, but chronic diseases. Everybody

was the subject of, or was going to be the subject of, bacterial disease. These forces would have to be got under control before we could consider our civilization complete. The triumphs of antiseptic surgery were great, but no drug had been discovered capable of killing microbes in the interior of the body. The modern method of immunization began with inoculation against smallpox, which was superseded by the discovery of vaccination. Pasteur devoted his life to the extension of this discovery—immunizing against disease. His name would be associated with prophylactic and phylactic inoculation. The next step was comparatively small. Given a localized disease, such as a boil, by phylactic inoculation, Sir Almroth had found that he could stir up the machinery of immunization and so cure it. Gradually he had applied this principle to other diseases. His conclusion was that given a localized disease and knowing the infective organism, immunization by a vaccine was always possible. In Sir Almroth's opinion, that would ultimately be the treatment of bacterial disease.

PARIS LETTER

(From Our Regular Correspondent)

PARIS, May 6, 1909.

The Reform of Instruction Question

The Association of Members of the Teaching Corps of the Faculties of medicine, whose foundation I chronicled in a previous letter (THE JOURNAL, April 10, 1909, p. 1192), at its first general assembly occupied itself with the question of the *agrégation*. The assembly discussed the question whether the test of admissibility should be by examination or by *concours*. The second solution (*concours*) was decided on by 156 votes against the 52 cast for the project of an examination conferring certificates. The assembly endorsed the position taken in the report of Professor Grasset of Montpellier, viz.: 1, that the admissibility, instead of being a degree or a definitive title, consisted only in a temporary right to the *concours*, limited to the three *concours* following the admission; 2, that the admissibility confers on those who have obtained it no other privilege than that of presenting themselves at the *concours* for admission to the *agrégation*, and does not allow them to be named without a *concours* for the posts of chief of clinic, substitute professor, etc., in the faculties and schools of medicine. The association of members of the teaching corps unanimously pronounced in favor of maintaining the *agrégation*, and of permanent tenure of the post of *agrégé* (at present the *agrégés* are appointed only for a period of nine years).

The Struggle Against Infant Blindness

The minister of the interior has issued to the prefects an important circular relative to the measures to be taken for the prevention of infantile blindness. Notwithstanding that the number of cases of ophthalmia neonatorum has sensibly diminished during ten years, much yet remains to be done in this field. The circular refers to the decree authorizing pharmacists to furnish midwives with a 2 per cent. solution of silver nitrate for preventive instillation in the eyes of the newborn. It recommends the utmost publicity for the following notice: "If the child's eyelids are red, swollen, or glued together, if there is any trickling of liquid or of pus, you may be sure that it does not come from a draught, but from a serious disease. You should suspect ophthalmia, which may make the child blind, and should cause it to be immediately examined and attended by a physician that very day." Finally, the circular calls on the prefects to organize in their departments a medical service for the prevention in school children of the disorders resulting from neglected myopia. It also insists on the necessity for suitably equipping both in personnel and material the local ophthalmologic clinics.

A permanent investigating committee for the aid of the blind, instituted by M. Mirman, director of assistance and public hygiene, has been at work for three months at the ministry of interior, and M. Clemenceau informed himself as to the views of this committee before issuing the above mentioned circular to the prefects.

The recent inaugural thesis of Dr. Jules Vergne on eye inspection in schools, brings strongly into view the gravity of the disease and the necessity for combating it with energetic measures. The following figures are taken from the statistics given by Dr. Vergne: in a *lycée* of the department of the Cher, out of 275 pupils examined only 130 were found normal; in a communal school in Paris, 85 children out of 202 showed a perceptible diminution of visual acuity.

Myopia is generally held to be of school origin. If it were really such, the districts where the illiterates are most numer-

ous should furnish the least myopies. Dr. Vergne, however, found entirely the opposite conditions prevailing, when arranging by departments according to the rules of revision the list of young men exempted from military service for myopia. But if the school is not the primary cause of myopia, it is none the less true that the average of myopia increases from class to class. The sight of the children, then, should be the object of constant care, and it is to be wished that eye inspection should form part of the medical inspection of schools, as it has done for some time in England. Thanks to the happy initiative of certain specialists, like Dr. Baudry of Lille, Professor Truc of Montpellier, Professor Motais of Angers, this inspection is already in operation in a certain number of towns.

BERLIN LETTER

(From Our Regular Correspondent)

BERLIN, April 28, 1909.

The Twenty-sixth Congress for Internal Medicine

The Congress for Internal Medicine met in Wiesbaden from April 19 to 22 under the presidency of the well-known clinician of Bonn, Professor Schultze. Nearly a hundred papers were announced and in spite of the fact that the special sessions were considerably prolonged, several members did not succeed in addressing the congress, on account of lack of time. Among the papers read the majority dealt with the circulatory system and metabolism. There is much activity in both of these fields at the present time in the German clinics, especially in those of Berlin, Munich, Heidelberg and Tübingen.

On the first day the only address was that of Prof. Magnus-Levy of Berlin, a young but meritorious investigator in the field of diseases of metabolism. He spoke on the subject of "The Metabolism of Mineral Substances in Human Pathology." Among the mineral substances calcium is of great importance for man, as its quantity varies in different diseases. In rickets there is present too little calcium; this does not depend, as was formerly believed, on the lack of calcium in the diet but on a disturbance of the function of the bone cells. Phosphorus, sulphur and iodine have a somewhat obscure relation to the human organism. On the other hand, of late years it has been shown that common salt has a very important influence. 15 to 20 gm. of sodium chlorid, which is usually the amount taken daily by healthy people, are excreted from the system within twenty-four hours. On the other hand, it has been shown by Widal of Paris and H. Strauss of Berlin that when the excretion of salt in patients with diseases of the kidneys diminishes dropsy occurs. On this fact Widal founded the treatment of nephritic dropsy by restriction of salt in the diet and clinical experience has shown that good results are obtained by this method in many cases. In other diseases also salt is influential in the treatment as for instance, in diseases of the circulatory system, and it has been shown that in the treatment of epilepsy by bromids after salt is excluded the action of the bromids is increased. Finally in nutritive disturbances of nurslings, it has been shown by the investigations of the Berlin pediatrician Finkelstein that fever with loss of albumin and fat may be produced by sodium chlorid and disappear on the withdrawal of that substance; eczema may arise from the same cause. On the conclusion of Magnus-Levy's address, Widal of Paris explained his method of "dechloruration" in disease of the kidney. How large an amount of salt is harmless to the patient must be determined in every case as from $\frac{1}{2}$ to 2 gm. a day are sufficient in many cases to make the food palatable. It is not necessary to give the dropsical nephritic patient an absolute milk diet, but a mixed diet may be given if the amount of salt is reduced to a proper degree. A number of other speakers, especially H. Strauss of Berlin, Bickel of Berlin and Gerhardt of Basel, discussed the subject of metabolism of mineral substances, but there is nothing special to note regarding their addresses.

Great interest attaches to the address of Professor Lenhartz of Hamburg on the third day regarding the treatment of gastric ulcer. For several years Lenhartz has departed from the Leube method and gives on the first day of treatment, even immediately after the cessation of hemorrhage, eggs and milk by the mouth. The hyperacidity which accompanies the ulcer is diminished by the albumin of the egg which combines with the hydrochloric acid and medicines for neutralizing the hydrochloric acid are unnecessary. The pain is also relieved by this diet, so that bismuth and morphin are not needed. As the patients are sufficiently nourished from the first day they are not so much reduced as by the ordinary method and there is less danger of death from asthenia which

is likely to happen after severe bleeding. The patient can leave the bed much sooner than usual. In order to compensate for the hemoglobin lost by hemorrhage Lenhartz gives his patient iron pills (Blaud's pills?) which are well borne according to his experience. In the discussion Leube spoke first. Notwithstanding the fact that the results of his many years' experience demonstrated the satisfactory character of his method of treatment, he concludes that one is justified from the communication of Lenhartz in putting patients on a solid diet sooner than heretofore; but for the first days of treatment the nutrient enemata are to be continued especially after hemorrhage. Most of the other speakers, v. Müller of Munich, Moritz of Strassburg, Gerhardt of Basel, Fleiner of Heidelberg, Krehl of Heidelberg, etc., took an intermediate view, but confirm from their own experience the claims of Lenhartz. Fleiner, however, adheres to the old plan of the Leube treatment in its entirety.

On the third day of the session the well-known London neurologist, Head, opened with an address on the subject, "Sensibility and the Testing of Sensibility." Head studied the disturbance of sensibility arising after section of the sensory nerves of his own left forearm, according to the methods developed by him and especially made a comparison of the disturbance during and after the regeneration of the nerves with those disturbances already determined. The details of this investigation must be omitted for lack of space.

From the great number of other papers I give only a brief notice of a few. The clinical significance of the electrocardiogram was much discussed and its value for the diagnosis of disturbance of the heart function was thoroughly recognized. Professor Hoffmann of Düsseldorf was of the opinion that the curves did not indicate the functional capacity of the heart but only the irritability of the heart muscle. Examination of the heart, lungs and digestive organs by the x-ray was demonstrated. Professor Goldscheider of Berlin described his method of graduated percussion of the lungs, with which he claims to have obtained better results than with the ordinary loud percussion. Professor Püssler of Dresden has carefully observed the condition of the mouth in certain affections which run their course with the picture of general intoxication and found that purulent affection of the pharyngeal tonsil or the teeth was the cause. By appropriate treatment of these organs the general symptoms were relieved.

Plesch, of Budapest, an assistant of Professor Kraus of Berlin, has devised a method by which it has been determined from the respired air that 4.5 liters of blood circulate in the body every minute and that 60 c.c. of blood are expelled from the cavities of the heart at each contraction. The blood moves with a velocity of 50 cm. in a second. A complete course of the blood through the body occurs in 55 seconds with 65 pulse beats. The heart performs in a minute the work of 14 meterkilograms; it is eight times better supplied with blood than the rest of the body. In anemic people the amount of blood circulating to a minute is raised to 20 liters. The heart of a healthy man in 60 years performs 350,000,000 meterkilograms of labor and expels from its cavities 2,800,000,000 liters of blood into the circulation.

Curschmann of Mainz draws attention to the fact that in threatened uremia in consequence of kidney disease the tendon and skin reflexes are markedly increased, a fact that may be of diagnostic importance. O. Müller, of Tübingen, from his investigation on the digitalis bodies, draws the conclusion that these preparations act only on the heart and not on the peripheral blood vessels. v. Tabora, of Strassburg, recommends in case of an overloading of the venous system, either a full venesection or to encircle the limbs with an elastic band, so that the blood may be temporarily excluded from the circulation. Schottelius reports favorable results from the treatment of dysentery with an antitoxic serum.

The next congress will be held in 1910, again in Wiesbaden. The president is Professor Kraus, of Berlin.

Work of the Berlin Medical Inspectors of Schools

Each school physician is required to visit quarterly each school placed under his charge. In the report of the president of the association of Berlin school physicians, which recently appeared, a protest is made against the use of a common drinking glass as, especially during the prevalence of an epidemic, there would be danger of conveyance of disease. The school carbonic acid baths are very much liked. Instruction in swimming is given to pupils without charge. The mis-use of alcohol has markedly diminished among the school children and now affects only a very small portion of the pupils. To obviate the disadvantage in sitting still during the classes a free movement is permitted in the ten-minute recesses.

Pharmacology

POSLAM

W. A. Puckner and W. S. Hilpert

[CONTRIBUTION FROM THE CHEMICAL LABORATORY OF THE AMERICAN MEDICAL ASSOCIATION.]

A number of inquiries having been received regarding the composition of "Poslam," the preparation was examined in the Association's laboratory. It is evident, from the letters received, that this nostrum is widely advertised. As physicians are likely to be questioned by their patients as to the therapeutic value, or lack of value of "Poslam," it is desirable that they should be in a position to express an intelligent opinion on the subject.

EXAMINATION OF THE PRODUCT

The preparation is found on the market in small three-quarter ounce "trial" tins, and in 5½ ounce jars bearing the name "Poslam," and the name of the manufacturers, "The Emergency Laboratories, 32 West Twenty-fifth street, New York City," with descriptive matter, in which it is stated that "the success of Poslam in the cure of eczema and all kindred skin diseases has been absolute. . . ."

Poslam as examined in the Association laboratory was found to be a gray ointment of the consistency of petrolatum and possessing an odor of oil of tar. Qualitative examination demonstrated the presence of zinc oxid, sulphur, starch, tar oil, menthol, salicylic acid and a fatty base, probably petrolatum. From the results of quantitative estimations it was concluded that the composition of Poslam was essentially as follows:

Zinc oxid	12.01 parts
Sulphur	6.67 parts
Corn starch	22.00 parts
Tar oil	15.18 parts
Menthol	Small quantity of each
Salicylic acid	
Fatty base q. s.	100 parts

From the results of the analysis it can be seen that the preparation depends for its action on such simple remedies as zinc oxid, sulphur and oil of tar. These have long been used and known as more or less effectual remedies for the treatment of skin affections, but certainly do not warrant such claims as are made in the advertising matter sent out with poslam stating it to be "The newest medical discovery for the treatment of eczema and all other skin affections" and " . . . entirely different from anything yet used . . ."

ANTINEURASTHIN

A New Use for Eggs and Milk

A German nostrum known as "antineurasthin" has been given—for a substantial consideration—many columns of space in British newspapers. This "cure for nervousness" is an "epoch-making discovery" of one Dr. Hartmann. According to the *Pharmaceutische Zeitung* the firm of "Dr. Hartmann" is one of a group of quack-medicine manufacturers against whom the chief of the Berlin police issued a public warning. The commercial possibilities of antineurasthin having thus received a substantial setback in the paternalistic Fatherland, the business, it appears, was transferred to Germany's more *laissez-faire* western neighbor across the North Sea, and we understand is about to appear in this country also.

THE ANALYTICAL "REPORT"

In any event antineurasthin has been heavily advertised as the cure for the "Twentieth Century Disease," and as a remedy that "directly combats the brain-cell and nerve-ganglionic cell degeneracy," whether this sad state of affairs is "due to overwork or mere malnutrition"! Testimonials of the most approved type and an elaborate "report" from an "analyst" with a long string of high sounding titles form part of the stock-in-trade. The editor of *London Truth*, having had occasion to pay his respects to this nostrum, was particularly struck by the positiveness of the statements

in the published "report" of this particular "analyst" regarding the virtues of antineurasthin; they read "a good deal more like the work of an advertisement-writer than that of a man of science." For instance, the "analyst" states in his report:

"Antineurasthin" does not only "relieve;" it cures by "feeding" the attenuated nerve cells, and thus after awhile, restored to their normal energy and vital powers, they are able to perform their brain and tissue-renewing functions again without external aid.

It is rather unusual for a chemist to express an opinion like the foregoing, on the medical properties of a preparation, based merely on a laboratory analysis. *Truth* sent a representative to the "laboratory" and found that it consisted of some rooms "somewhere upstairs" in the private house at which the "analyst" lodged. The "analyst" himself was not at home and all the landlady could tell about the "Chemical and Physical Laboratories" was that her lodger had "a quantity of bottles" and other paraphernalia in his apartment, "with which he occasionally made appalling smells."

WHAT IS ANTINEURASTHIN?

As to what this "cure for nervousness" is, there seems to be a difference of opinion. According to the manufacturer:

Antineurasthin itself is a scientifically compressed compound of the Myelline (or Lecithine) elements of certain costly foods, especially rich in this valuable brain-building constituent of the best of our daily foods.

But the *British Medical Journal*, which had the stuff analyzed suggests that the composition of this marvelous renewer of brain energy is approximately as follows:

Dried yolk of egg	3.8 per cent.
Dried white of egg	5.4 per cent.
Dried separated milk	57.8 per cent.
Gum	2.0 per cent.
Potato starch	22.7 per cent.
Moisture	8.3 per cent.
Aromatic substances	Traces

The daily dose of four tablets or 122 grains would, according to this formula, contain the equivalent of 10 grains of yolk and 43 grains of white of egg (not dried); the ratio between these is about the same as exists in an average egg and the two may be put together and regarded as about a teaspoonful of fresh egg; in addition the daily dose would represent about 2 oz., or a quarter of a tumblerful, of separated milk and a little starch.

In extolling the "lecithine elements of certain costly foods" of which its product is said to consist, one wonders whether the Antineurasthin Company is guilty of a subtle joke in thus referring to the outrageously high price of hen's eggs during the past winter! As to the ethics of selling eggs and milk under a fancy name and for a still more fancy price, as a cure of nervousness, we can not do better than quote from the article in *Truth*, already referred to, and which bears the caption, "Hens' Eggs and Nerve Trouble."

"What the public should understand, however, is that most preparations of this kind are based on some remedy, the efficacy of which in certain cases is well-known. In this particular instance the remedy seems to be yolk of egg. The great discovery of Dr. Hartmann converts the domestic hen into a rival of the goose that laid the eggs of gold. The *modus operandi* is worth the attention of poultry farmers. You dry your hens' eggs; you mix them up with plenty of starch, separated milk, or other harmless ingredients; you get a few imposing testimonials and reports from parties who deal in such articles; you engage a smart advertisement-writer, prime him with a little fact and a great deal of scientific jargon; you rent as many pages or columns in the press as you can afford; and your hens' eggs hatch out into handsome dividends. The Twentieth Century Disease, however, goes on as before. My own impression is that quite the worst disease of the twentieth century is the disposition to swallow excessive quantities of preparations of this character, and equally excessive quantities of the newspaper advertisements relating to them."

The Examination in Children.—K. H. Goldstone advises examination of the eye fundus in any child who after the fifth year fails to hold up its head, who does not grasp objects, or whom autism is present. He believes that amaurotic blindness is rare as was formerly thought.—

Miscellany

The New Building of the Medical and Chirurgical Faculty of Maryland

The new building of the Medical and Chirurgical Faculty of Maryland, noted editorially in *THE JOURNAL*, May 13, p. 1580, is the first to be erected by a state medical society in the United States and will be a suitable meeting-place for the society as well as a safe depository for the new library. The dedication will be reported in connection with the state society meeting.

For many years the Medical and Chirurgical Faculty of Maryland has been housed in an ordinary three-story dwelling-house where the meeting halls were too small and the book shelves overcrowded. The contributions for the building have been made by members of the society and public-spirited citizens both toward the general building fund and also to a separate fund contributed as a testimonial to Dr. Osler. In addition, the General Assembly of Maryland, in 1908, voted a donation of \$12,500.

The building is the result of much study, both of the needs of such a building, and of other libraries. The chief feature that the committee had in view was to combine a medical building for a meeting-place for the members of the society and for instructive lectures to the public, and an endeavor was made to have the meeting rooms confined to the first floor. The second feature was to have a quiet place for reading where there would be little or no noise or confusion. The book stack is unique in that very little light from the outside has been permitted, there being only a few small windows, so that the books are protected from the action of light.

The property on which the library stands has a frontage of sixty-six feet on the east side of Cathedral street between Preston and Biddle streets, and runs through to Maryland avenue with a depth of two hundred and forty-six feet.

The building itself is a fire proof construction of reinforced concrete and brick, having a facade of about 50 feet in height, with a pilaster treatment above, and a basement story on the street level. The treatment is of the Georgian or English colonial type of architecture executed in granite, limestone, terra cotta and brick; the brick work is laid in Flemish and English bond. The entrance to the building is through a vestibule with a marble base and architraves, to the main corridor leading to the stairs and principal rooms. On the right on entering there are two rooms that will be used by the registry for nurses under the direction of the Maryland Association for Nurses. On the left is a room dedicated to the late Dr. Aaron Friedenwald, handsomely furnished in oak and brown leather, and to be used as a conversation room. Back of this is a small meeting hall, with a seating capacity of about 150. Again on the right are the committee, cloak and toilet rooms, and a handsome stairway of solid masonry with marble steps and mahogany handrail, with a wrought iron balustrade, and well-lighted by a skylight and windows.

The new building of the Medical and Chirurgical Faculty of Maryland.

At the end of the corridor, opposite the front door, is the main auditorium, having a seating capacity of 500, well-lighted by windows at the back and by a large skylight in the vaulted ceiling. The two halls are so arranged that the two may be used together to accommodate unusually large audiences.

The basement of the building contains ample space for the storage of books, manuscripts and reports, and also has a shipping and receiving department; and contains the heating apparatus. Connected with the basement corridor through wide glazed doorways is a supper room of ample size, equipped with kitchen and pantries.

On the second floor of the building extending across the whole front is the main reading-room, known as the "Frick Room," having a high ceiling with beams and an elaborate cornice and wainscot of green material trimmed with mahogany, with a handsome fire place and mantel at one end of the room and a gracefully arched alcove at the other. This room is furnished in mahogany, with easy chairs, writing

tables and other conveniences for the use of the readers. Opening from this room is the periodical room, and back of this the librarian's office, and between this and the book stack is the cataloging room.

The back of the main building, which does not include the principal auditorium mentioned above, is given up to the stack room, which is designed after the most modern models, is fitted with the best Snead metal fireproof stacks and has a capacity of 70,000 volumes; it can be entered only through a fireproof door from the cataloging room and is practically a solid vault of concrete, brick and steel.

On the third floor are five large rooms, one of which will be used for a clinical laboratory for the use of the members, the others for section meetings and committees.

The fourth floor is not visible from the front and contains housekeeping apartments for the librarian and assistant, complete in every detail of convenience and equipment.

Origin of the Outbreak of Foot-and-Mouth Disease

The Bureau of Animal Industry of the U. S. Department of Agriculture has just published the result of the investigation of the origin of foot-and-mouth disease among cattle which prevailed during the early part of last winter. An abstract of the report furnished by the bureau is as follows:

The recent outbreak of foot-and-mouth disease in Michigan, New York, Pennsylvania and Maryland started from calves used in the propagation of smallpox vaccine virus which had been contaminated with the virus of foot-and-mouth disease, and the contaminated strain of vaccine originally came from a foreign country. These are the conclusions from an investigation made jointly by the Bureau of Animal Industry of the Department of Agriculture and the Public Health and Marine-Hospital Service of the Treasury Department, a report of which has just been issued. The investigation was conducted by Dr. John R. Mohler, chief of the Pathological Division of the former bureau, and Dr. M. J. Rosenau, director of the Hygienic Laboratory of the latter bureau.

SURGICAL DISEASES OF CHILDREN. By Samuel W. Kelley, Professor of Diseases of Children, Cleveland College of Physicians and Surgeons. Cloth. Pp. 768, with illustrations. Price, \$5.00. New York: E. B. Treat & Co., 1909.

A book devoted to surgical pediatries is something new. Ordinarily the subjects are covered in works on orthopedic surgery and general surgery. Dr. Kelley's implied reason for the creation of this new general subject is that of all surgical disorders of children, some are found only in children, some are found most often in children, and the rest are modified by occurrence in children. Thus surgical pediatries, as a subject separate from general surgery, is justified in the same way as medical pediatries as separate from general medicine, but differently from the justification of orthopedic surgery which is identified by dealing only with certain structures, and not only with a certain age.

The book systematically covers examination of children, surgical pathology of childhood, general infections, fractures and other traumas; all congenital and acquired deformities, bone and joint diseases, and regional surgery in children. The book is well illustrated, the twenty-six page index, an important part of any large book, is carefully prepared, and Dr. Kelley's tone is judicious, personal and not unduly authoritative, for no one man can be authority for such a long range of subjects.

A MANUAL OF CLINICAL DIAGNOSIS. By James Campbell Todd, Ph.D., M.D., Associate Professor of Pathology, Denver and Gross College of Medicine (University of Denver). Flexible Leather. Pp. 318, with illustrations. Price, \$2.00. Philadelphia: W. B. Saunders Co., 1908.

This manual is well adapted to be a guide to the clinical laboratory work of the general practitioner. The methods are practical and are selected on the principle that it is better to learn one method well than to be acquainted superficially with any. The book is convenient in size and well illustrated, which adds greatly to the value of such a work.

A TEXT-BOOK OF MEDICAL CHEMISTRY AND TOXICOLOGY. By James W. Holland, A.M., M.D., Professor of Medical Chemistry and Toxicology, and Dean, Jefferson Medical College, Philadelphia. Second Edition. Cloth. Pp. 655, with illustrations. Price, \$3. Philadelphia: W. B. Saunders Co., 1908.

The second edition of Dr. Holland's text-book presents a thorough revision, which brings it in accord with the recent edition of the United States Pharmacopeia and the advances in physiologic chemistry. Few medical students enter on their course with a thorough understanding of general chemistry; and this fact makes it necessary to devote a large part of the work—more than half—to general chemical principles and the chemistry of the elements. The treatment, however, is specially suited to the requirements of the medical student. The sections dealing with organic and physiologic chemistry include the methods of analysis of the gastric contents, milk and urine. The tests given are such as will be practically useful. While the revision has introduced the most recent methods, it is a little disappointing to find antiquated methods like Ewald's salol test and the use of potassium iodid to determine the absorptive power of the stomach still retaining a place in so excellent a text-book.

A SYSTEM OF MEDICINE. Vol. 4. Parts 1 and 2. By Many Writers. Edited by Sir Clifford Allbutt, K.C.B., M.A., M.D., LL.D., D.Sc., F.R.C.P., F.R.S., F.L.S., F.S.A., Regius Professor of Physic in the University of Cambridge, and Humphry Davy Rolleston, M.A., M.D., F.R.C.P., Senior Physician, St. George's Hospital, Cambridge. Cloth. Price, \$3 per volume. New York: The Macmillan Co., 1908.

This volume iv has been divided into two parts: The sections on diseases of the nose, pharynx and larynx have been expanded and combined with a section on diseases of the ear to form a separate volume. Some new articles have been introduced and the subjects treated in the previous edition brought up to date. No extensive review or commendation of this valuable and well-known work is necessary. The inclusion of diseases of the ear in a work on general medicine, while unusual, seems eminently appropriate, both on account of the intimate relations of the ear with the brain, and also because the general practitioner will naturally desire to find in his treatise on medicine such an account of ear diseases as will enable him to treat successfully such patients as need not be referred to a specialist.

Association News

CLINICS AT PHILADELPHIA

Series of Clinics and Demonstrations Arranged for Those Who Go to Atlantic City

THE JOURNAL has received the following announcements:

MEDICO-CHIRURGICAL COLLEGE

The Medico-Chirurgical College of Philadelphia cordially invites any members of the American Medical Association to visit the institution on their way to or from Atlantic City, and to attend the special clinics as indicated below:

Monday, June 7

- 9 a. m. Internal Medicine, Prof. James M. Anders.
- 10 a. m. Surgery, Prof. William L. Rodman.
- 11 a. m. Surgery, Prof. William L. Rodman.
- 12 m. Orthopedics, Prof. James P. Mann.
- 1 p. m. Ophthalmology, Prof. L. Webster Fox.
- 3 p. m. Internal Medicine, Prof. Judson Daland.

Saturday, June 12

- 10 a. m. Obstetrics, Prof. W. Frank Haehtlen.
- 11 a. m. Surgery, Prof. Ernest Laplace.
- 12 m. Genitourinary Diseases, Prof. H. M. Christian.
- 1 p. m. Pediatrics, Prof. W. C. Hollopeter.
- 3 p. m. Otology, Prof. Edward B. Gleason.

Other clinics will be arranged for Monday, June 14, if desired by any of the visitors.

The members of the Association are also cordially invited to attend the Alumni Reunion and Smoker of the Medico-Chirurgical College on the evening of Tuesday, June 8, which will be held at the Hotel Rudolf, on the Boardwalk, at Atlantic City.

SAMARITAN HOSPITAL

The staff of the Samaritan Hospital, Broad and Ontario streets, Philadelphia, will give clinics for visiting physicians as follows:

Monday, June 7

- 11-12 a. m. Medical Clinic, Dr. I. Newton Snively.
- 12-1 p. m. Gynecologic Clinic, Dr. Frank C. Hamond.
- 1-2 p. m. Exhibition of Gynecologic Specimens, Dr. Harry A. Duncan.
- 2-3 p. m. Rectal Clinic, Dr. Collier F. Martin.
- 3-4 p. m. Ear, Nose and Throat Clinic, Dr. Nathan G. Ward.
- 4-6 p. m. Surgical Clinic with Demonstrations of Spinal and Narcotic Anesthesia, Dr. W. Wayne Babcock and Dr. William A. Steele.

Saturday, June 12

- 11-12 a. m. Obstetric Clinic, Dr. John C. Applegate.
- 12-1 p. m. Gynecologic Clinic, Dr. Wilmer Krusen.
- 1-2 p. m. Pediatric Clinic, Dr. James H. McKee.
- 2-3 p. m. Medical Clinic, Dr. Samuel Wolfe.
- 3-4 p. m. Ophthalmic Clinic, Dr. Wendell Reber.
- 4-5 p. m. Surgical Clinic, with Demonstrations of Spinal and Narcotic Anesthesia, Dr. W. Wayne Babcock.
- 5-6 p. m. Genitourinary Clinic, Dr. William A. Steele.

Correspondence

A National Home for Aged or Invalid Physicians

To the Editor:—The establishment of a national home for aged, incapacitated and invalid physicians is a question which can profitably be considered by the American Medical Association. The broad humanitarianism of such a plan should appeal to our membership; its practicability should insure an early investigation and a report of its advisability.

The project is feasible. That has been demonstrated by labor unions and fraternal orders. In 1892, the Union Printers' Home, the pioneer of such institutions, was dedicated at Colorado Springs, Colo. In the seventeen years which have elapsed since that time every cent of the \$800,000 which has been spent in maintenance and in permanent improvements, with the exception of a \$10,000 gift and an endowment of \$1,000, has come from the ranks of the union. The monthly assessment on each of the 45,000 members was originally ten cents; this was increased a few years ago to fifteen cents, which means half a cent a day, or less than the amount an average printer will earn in a minute's working time. This provides an annual fund of nearly \$90,000. More than 1,000 members have been admitted to the Printers' Home; the average number of residents is 150; and the average cost per month \$30. The property has a valuation of \$1,000,000.

The Modern Woodmen of America, with a membership of 1,000,000, has this winter opened its national sanatorium for the treatment of tuberculosis, north of Colorado Springs. This institution will ultimately involve an expenditure for personal improvements of \$500,000 or more, and will provide accommodations for 500, or possibly 1,000 patients. It costs every member of the order ten cents a year.

With a membership of about 32,000, the American Medical Association is assured of ample support in undertaking to build and maintain an institution of this character. An assessment of \$2.50 the first year would provide all the money necessary for the purchase of a site and the erection of the necessary buildings. After that, a monthly assessment of five or ten cents would adequately maintain the home.

Such an institution would fill a want in the membership of the Association. To the physician who is no longer able to engage in the practice of his profession because of broken health, it would offer a retreat where he could build up his lost strength and vitality under the most favorable of conditions; to the aged practitioner who still is required by force of circumstances to continue his daily work at a time when his years of active service should entitle him to a rest, it would be a haven of peace. The matter of planning the institution on such broad lines that provision might be made for the care of the families of those who seek its shelter is one that should be given the most careful attention.

This is a humanitarian project of the highest type; it is not charity. Every member of the American Medical Association, on doing his share in the establishment and maintenance of the institution, would by right feel that it truly should be and would be his home should the vicissitudes of life, from which none of us are immune, ever give him reason to seek its kindly shelter. This is a matter which is deserving of the most careful consideration of our membership, and I present it at this time that it may come up for preliminary discussion at least, at the forthcoming convention at Atlantic City.

A. C. MAGRUDER, M.D., Colorado Springs, Colo.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS will not be noticed. Queries for this column must be accompanied by the writer's name and address, but the request of the writer not to publish name or address will be faithfully observed.

METHOD OF DETERMINING DIASTOLIC BLOOD PRESSURE

To the Editor:—I have just been reading two articles in German periodicals describing the determination of diastolic blood pressure by the auscultatory method. When I was in Germany last summer, I learned this method from a young German physician in Naumburg and have successfully used it with interest ever since. In none of these articles is mentioned this method, which I have found in practice to be much simpler than any other and just as accurate.

The method is this: After the physician has determined the systolic pressure by some method involving the circulatory compression of the arm, he relaxes the pressure and says to the patient, "At one time during the examination, you felt a very distinct throbbing of the arm. Now I am going to make the determination over again and I want you to tell me as soon as that throbbing returns to as great an extent as you felt it at any time." Then the physician gradually makes pressure on the arm and when the patient says, "Now I feel the throbbing to as great an extent as before," the physician reads the diastolic pressure.

I have tested this method in comparison with the other methods and my personal belief is that with the instruments so far invented, it will be found, in the hands of most observers, more correct than any of them. Of course most of my own experience has been with my own blood pressure apparatus, using hydrostatic pressure as shown in the accompanying illustration.

I therefore enumerate the diastolic pressure determination methods as follows: (1) the tactile method; (2) the graphic method; (3) by the observation of the fluctuations of pressure; (4) the auscultatory method; (5) the subjective pulsation method, which I employ.

LOUIS FALGÈRES BISHOP, 54 West 55th St., New York

DISINFECTION BY FORMALDEHYD

To the Editor:—Please tell me how formaldehyd and potassium permanganate are used in combination as a germicide, and what is the result of the combination.

ANSWER—This method was described in THE JOURNAL, July 14, 1906, xlvii, 139, and Jan 12, 1907, xlviii, 159. The action between the potassium permanganate and a part of the formaldehyd produce enough heat to volatilize the greater part of the formaldehyd as formaldehyd gas, which is the disinfecting agent.

RUOTTE'S ANASTOMOSIS OF SAPHENOUS VEIN TO PERITONEUM

To the Editor:—In THE JOURNAL (Nov 14, 1908, II, 1662), which I have had the pleasure of taking for two years, there is a paper by Alexis Carrel, entitled "Results of the Transplantation of Blood Vessels, Organs and Limbs," in which the following passage appears: "Ruotte cut the saphenous vein and sutured its peripheral end to the peritoneum in a case of chronic ascites. The ascites disappeared." As there is no further mention of the said Ruotte, I apply to you for any possible information in regard to Ruotte's paper.

L. SLAVINSKI, M.D., Warsaw, Poland, Russia

ANSWER—Ruotte published his work on the treatment of chronic ascites by anastomosis of the saphenous vein to the peritoneum in *Lyon médical*, 1907, page 574. The title of the paper is "Abouchement de la veine saphène au péritoine comme traitement de l'ascite." In a case of cirrhosis of the liver, the ascites reproduced itself very quickly after puncture. Ruotte dissected and cut the saphenous vein 8 cm below its mouth, and sutured its peripheral end to the peritoneum just above Poupart's ligament. The ascites disappeared. Several months after the operation, the patient was in good condition and the ascites had not reappeared. In another case, the patient was in a very bad general condition and died a few days after the operation. Post-mortem examination showed that the saphenous vein was normal. On the peritoneum, a little infundibulum was seen at the place of its anastomosis to the saphenous vein. A catheter could easily be introduced from the peritoneum to the femoral vein through the saphenous vein.

The Public Service

Army Changes

Memoandum of changes of stations and duties of medical officers, U S Army, week ended May 17, 1909.

Hanson, L. H., 1st lieutenant, granted leave of absence for fourteen days.

Woodson, R. S., major, granted leave of absence for four months.

Russell, F. F., major, ordered to Philadelphia and New York City, on business of the Medical Department, and then to return to Washington.

Schmittler, Ferdinand, 1st lieutenant, granted leave of absence for ten days.

Whitmore, E. R., capt., detail with Bureau of Science, Department of the Interior, Philippine Islands, extended one year.

Feld, Peter C., capt., ordered to duty at a military tournament at Toledo, Ohio, June 26, 1909.

Chambelain, W. P., major, granted leave of absence for ten days.

Love, Albert G., 1st lieutenant, granted leave of absence for fourteen days.

Crosby, E. D., lieutenant colonel, Kean, J. R., lieutenant colonel, Ireland, M. W., major, Russell, F. F., major, detailed to represent the medical department of the Army at the meeting of the American Medical Association at Atlantic City, N. J., June 8 to 11.

Thomason, H. D., capt., relieved from duty at Fort Douglas, Utah, and ordered to Fort Missoula, Mont., for duty.

Navy Changes

Changes in the Medical Corps, U S Navy, for the week ended May 17, 1909.

Nash, F. S., surgeon, ordered to additional duty at the Marine Recruiting Station, Philadelphia.

Mintz, J. M., asst surgeon, detached from the Naval Recruiting Station, Cincinnati and ordered to the Naval Medical School Hospital, Washington, D. C. for treatment.

Gudner, J. E., Medical inspector, ordered to additional duty at the Naval Recruiting Station, Boston.

Brynes, J. C., medical inspector, detached from the West Virginia and ordered to the *Unconsc* as fleet surgeon of the Pacific Fleet.

Porter, F. C. P., A surgeon detached from the Naval Recruiting Station, Boston, and ordered to the Naval Station, San Juan, P. R. sailing from New York May 22.

Turner, H. W. B., asst surgeon, detached from the *Hancock* and ordered to the *Paducah*, sailing from New York about May 21.

Pauntlerov, A. M., P. A surgeon, detached from Marine Recruiting Office, Philadelphia, and ordered to the *Hatford*.

Health Reports

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon General, Public Health and Marine Hospital Service, during the week ended May 14, 1909.

SMALLPOX—UNITED STATES

California: Berkeley, April 17-24, 1 case; Oakland, April 10-26, 2 cases; Sacramento, March, 1-31, 2 cases.
 Georgia: Macon, April 25-May 2, 7 cases.
 Illinois: Danville, April 25-May 2, 8 cases; Galesburg, April 24-May 1, 1 case; Springfield, April 23-30, 1 case.
 Indiana: Fort Wayne, April 17-24, 1 case; Indianapolis, April 25-May 2, 1 case; La Fayette, April 26-May 3, 3 cases; South Bend, April 25-May 1, 3 cases.
 Iowa: Cedar Rapids, April 1-30, 2 cases; Council Bluffs, April 25-May 3, 1 case; Sioux City, April 1-30, 1 case.
 Kansas: Kansas City, April 25-May 1, 1 case; Wichita, 4 cases.
 Kentucky: Lexington, April 25-May 1, 2 cases.
 Louisiana: New Orleans, April 25-May 1, 5 cases.
 Minnesota: Duluth, April 22-29, 2 cases.
 Missouri: St. Louis, April 25-May 1, 1 case.
 Montana: State of, March 1-31, 55 cases.
 Nebraska: South Omaha, April 3-10, 1 case.
 New Jersey: Trenton, April 25-May 1, 2 cases.
 New York: Niagara Falls, April 25-May 1, 1 case.
 Ohio: Ashtabula, April 25-May 1, 6 cases; Cincinnati, April 23-30, 18 cases; Cleveland, 1 case.
 Tennessee: Knoxville, April 25-May 1, 13 cases.
 Texas: Hidalgo County, Jan. 15-April 1, 16 cases; San Antonio, April 25-May 1, 4 cases.
 Utah: State of, March 1-31, 136 cases.
 Washington: Spokane, April 17-24, 6 cases.
 Wisconsin: La Crosse, April 25-May 1, 1 case; Superior, 3 cases.

SMALLPOX—INSULAR

Philippine Islands: Manila, March 13-20, 4 cases, 2 deaths.

SMALLPOX—FOREIGN

Brazil: Bahia, March 13-27, 8 cases, 2 deaths; Pernambuco, March 1-15, 5 deaths.
 Canada: Halifax, April 17-24, 1 case; Toronto, Feb. 27-April 17, 14 cases.
 Ceylon: Colombo, Dec. 12-Jan. 16, 64 cases, 12 deaths.
 China: Amoy, March 20-27, present; Hongkong, March 20-April 3, 2 cases.
 France: Paris, April 10-17, 1 case.
 India: Bombay, March 30-April 6, 17 deaths; Calcutta, March 20-27, 446 deaths; Madras, March 27-April 2, 3 deaths; Rangoon, March 20-27, 3 deaths.
 Indo-China: Saigon, March 14-21, 2 cases, 1 death.
 Italy: General, April 10-18, 61 cases; Catania, April 10-17, 1 case; Naples, April 11-18, 11 cases.
 Java: Batavia, March 13-20, 3 cases.
 Mexico: Guadalajara, April 15-22, 1 death; Mexico City, Feb. 27-March 27, 91 deaths; Monterey, April 18-25, 8 deaths; Veracruz, 2 cases, 2 deaths.
 Persia: Karmanshah, Feb. 17-March 17, 22 deaths.
 Portugal: Lisbon, April 10-17, 6 cases.
 Russia: Batoom, Feb. 1-28, 1 case; Moscow, March 27-April 10, 52 cases, 23 deaths; Riga, April 10-17, 2 cases; Warsaw, Feb. 6-13, 2 deaths.
 South Africa: Durban, March 20-27, 1 case, imported.
 Spain: Almeria, March 1-31, 1 death; Barcelona, April 12-19, 1 death.
 Straits Settlements: Penang, March 20-27, 1 case, imported.
 Switzerland: Zug, canton, April 11-17, 1 case.
 Tripoli: Tripoli, March 27-April 10, 90 cases, 10 deaths.
 Uruguay: Montevideo, Feb. 1-28, 11 deaths.

YELLOW FEVER

Brazil: Bahia, March 13-27, 21 cases, 12 deaths; Pernambuco, March 1-15, 1 death.
 Ecuador: Guayaquil, March 27-April 3, 18 deaths.
 Mexico: San Barnardo, vicinity of Maxcanu, April 24-May 1, 1 case; Ticul, April 10-17, 2 cases.

CHOLERA—INSULAR

Philippine Islands: Provinces, March 13-20, 118 cases, 72 deaths.

CHOLERA—FOREIGN

Ceylon: Colombo, Dec. 12-Jan. 2, 4 cases, 3 deaths.
 India: Bombay, March 27-April 6, 14 deaths; Calcutta, March 20-27, 143 deaths; Madras, March 27-April 2, 3 deaths; Rangoon, March 20-27, 4 deaths.
 Russia: St. Petersburg, April 16-21, 22 cases, 2 deaths.

PLAGUE

Brazil: Bahia, March 13-27, 5 cases, 1 death.
 China: Hongkong, March 20-April 3, 11 deaths.
 Russia: General, April 2-8, 2 cases, 1 death.
 India: General, March 20-27, 6,059 cases, 5,035 deaths; Bombay, March 30-April 6, 407 deaths; Calcutta, March 20-27, 6 deaths; Rangoon, March 20-27, 16 deaths.
 Japan: Formosa, island, March 13-27, 99 cases, 85 deaths; Kobo, vicinity, March 27-April 3, 1 case.
 Mauritius: Port Louis, Jan. 1-31, 12 cases, 12 deaths.
 Straits Settlements: Singapore, March 13-20, 1 death.
 Turkey: Jiddah, April 19-21, 1 case, 2 deaths.

Public Health and Marine-Hospital Service

List of changes of stations and duties of commissioned and other officers of the Public Health and Marine-Hospital Service for the seven days ended May 12, 1909:

Carmichael, D. A., surgeon, granted 14 days' leave of absence from May 26, 1909.
 Wertenbaker, C. P., surgeon, detailed to represent the Service at the annual meeting of the National Association for the Study and Prevention of Tuberculosis to be held in Washington, D. C., May 13-15, 1909.

Lavinder, C. H., P. A. surgeon, granted 4 days' leave of absence en route to Columbia, S. C.

Lumsden L. L., P. A. surgeon, granted 7 days' leave of absence from May 10, 1909, under paragraph 191 Service Regulations.

Warren, B. S., P. A. surgeon, detailed to represent the Service at the meeting of the Arkansas State Medical Society to be held at Pine Bluff, Ark., May 19-21, 1909.

Collins, G. L., P. A. surgeon, granted 3 days' leave of absence from April 30, 1909, under paragraph 189 Service Regulations.

Pettyjohn, Joseph, P. A. surgeon, on arrival of Asst.-Surgeon J. R. Hurley, directed to proceed to San Francisco.

Marshall, E. R., asst.-surgeon, granted 2 days' leave of absence from May 13, 1909.

Ames, R. P., acting asst.-surgeon, directed to proceed to Gualan, Guatemala, and other places on line of Guatemala Railway to observe sanitary conditions.

Poster, J. P. C., acting asst.-surgeon, granted 4 days' leave of absence from May 13, 1909.

Goldsborough, B. W., acting asst.-surgeon, granted 5 days' leave of absence from May 12, 1909, without pay.

Hume, Lea, acting asst. surgeon, directed to proceed to Del Rio, Texas and vicinity.

Rodman, John C., acting asst.-surgeon, granted 14 days' extension of leave from April 13, 1909, on account of sickness.

Stearns, H. H., acting asst.-surgeon, granted 2 days' leave of absence, April 12 and 14, 1909, under paragraph 210, Service Regulations.

Terry, M. C., acting asst.-surgeon, granted 2 days' leave of absence from April 18, 1909.

BOARDS CONVENED

Board of medical officers convened to meet at the Marine Hospital office Galveston, Texas, May 12, 1909, for the purpose of making a physical examination of an applicant for the position of cadet in the Revenue-Cutter Service. Detail for the board: P. A. Surgeon G. M. Corput, chairman; Acting Asst.-Surgeon Wm. H. Gammon, recorder.

Board of medical officers convened to meet at the Marine Hospital, Baltimore, as soon as practicable, for the purpose of making a physical examination of an applicant for the position of cadet in the Revenue-Cutter Service. Detail for the board: P. A. Surgeon G. M. Corput chairman; Acting Asst.-Surgeon Wm. H. Gammon, recorder.

Board of medical officers convened to meet at the Marine Hospital, Baltimore, as soon as practicable, for the purpose of making a physical examination of a First Lieut., U. S. Revenue-Cutter Service. Detail for the board: Surgeon W. P. McIntosh, chairman; P. A. Surgeon G. M. Corput, recorder.

Board of medical officers convened to meet on May 15, 1909, for the purpose of making physical examinations of officers of the Revenue-Cutter Service for promotion, as follows:

Portland, Me. Surgeon P. C. Killoch, chairman; Acting Asst.-Surgeon A. F. Stuart, recorder.

Boston. Surgeon L. L. Williams, chairman; Passed Asst.-Surgeon T. W. Salmon, recorder.

New York. Passed Asst.-Surgeon C. W. Vogel, Chairman; Asst.-Surgeon F. A. Ashford, recorder.

Baltimore. Surgeon, W. P. McIntosh, chairman; P. A. Surgeon M. K. Gwyn, recorder.

Norfolk, Va. P. A. Surgeon G. L. Collins, chairman; Acting Asst.-Surgeon R. W. Browne, recorder.

Galveston, Tex. P. A. Surgeon G. M. Corput, chairman; Acting Asst.-Surgeon W. P. McIntosh, recorder.

Board of medical officers will be convened to meet at the Bureau of Marine-Hospital Service, May 14, 1909, for the examination of applicants for the position of Assistant Surgeon in the Public Health and Marine-Hospital Service.

Marriages

HAROLD WARD DANA, M.D., to Miss Gertrude Veronica Quinn, both of Boston, May 6.

HARRY R. SPICKERMON, M.D., to Mrs. Lela Fay Spickerman, both of Muncie, Ind., recently.

GEORGE ROGER MYERS, M.D., Hurlock, Md., to Miss Edna Wright, at Hurlock, April 28.

ROLAND B. MACON, M.D., to Mrs. Adele Slayden Cross, both of Clarksville, Tenn., May 4.

WILLIAM A. RAIMAN, M.D., to Miss Rebecca Checkwood, both of Swarthmore, Pa., recently.

ARTHUR MARRIOTT SHIPLEY, M.D., to Miss Julia Armistead Joynes, both of Baltimore, May 6.

JOSEPH EDWARD PIIRUNE, M.D., Cincinnati, to Miss Adele Heile, of Covington, Ky., April 20.

WILLIAM C. ELLIOTT, M.D., Holly Springs, Miss., to Miss Mary A. Hughes, of Memphis, recently.

ARTHUR RANDOLPH GREEN, M.D., to Miss Florence Elizabeth Seeley, both of New York City, May 5.

FERDINAND LEO KIEFFER, M.D., Covington, Ky., to Miss Bertha Grau of Newport, Ky., May 5.

M. HEMINWAY MERRIMAN, M.D., New York City, to Miss Mallory Betts, of Norwalk, Conn., May 3.

JAMES ROYDAN PEABODY, M.D., Colorado Springs, to Miss Annie Hodgson Long of Louisville, Ky., May 11.

Deaths

John M. Boyd, M.D. University of Pennsylvania, Philadelphia, 1856; a member of the American Medical Association; surgeon in the Confederate service throughout the Civil War; chief of staff of the Knoxville (Tenn.) General Hospital since its foundation; president of the board of trustees of the Tennessee Deaf and Dumb School; a member of the board of trustees of the University of Tennessee; died at his home May 16, aged 75.

Henry Albert Crandall, M.D. Castleton (Vt.) Medical College, 1859; a member of the Vermont State Medical Society and a charter member of the Burlington Medical and Surgical Club; physician to the Mary Fletcher Hospital, Burlington; assistant surgeon of the Sloan General Hospital, Montpelier, during the Civil War; in 1891 health officer of Burlington; died at his home from cerebral hemorrhage, May 6, aged 77.

Dorrance William Aldrich, M.D. Bellevue Hospital Medical College, New York City, 1874; a member of the American Medical Association; a veteran of the Civil War; in 1886 appointed local surgeon for the Burlington System at Galesburg, Ill.; in 1876, 1880 and 1884, coroner of Knox county for two-year terms; and once mayor of Galesburg; died at his home, May 8, aged 63.

Charles John Sharretts, M.D. College of Physicians and Surgeons, New York City, 1878; of New York City; attending physician to the Montefiore Home; visiting physician to the Church Charities Hospital, Astoria, L. I.; for many years examiner for the Metropolitan Life Insurance Company; died at his home in Flushing, L. I., May 7, aged 54.

Roger Brooke, M.D. University of Maryland, Baltimore, 1887; a member of the American Medical Association, and once vice-president of the Medical and Chirurgial Faculty of Maryland; died at his home near Sandy Spring, Md., May 9, from heart disease, aged 63.

James McMahon, M.D. Upper Canada School of Medicine, Toronto, 1850; for fifteen years chief of the law stamp office, Osgoode Hall, Toronto; and from 1875-1894 member of the Provincial Parliament for North Wentworth; died suddenly at his home in Toronto, April 23, from cerebral hemorrhage, aged 87.

I. Winslow Ayer, M.D. Eclectic Medical Institute, Cincinnati, 1860; of Northville, Mich.; who during the Civil War, practically unassisted and impelled only by patriotism, unmasked the "Confederacy of the Northwest;" died in the Wayne County Hospital, April 29, aged 83.

William Peale Brewer, M.D. Medical College of Virginia, Richmond, 1864; of New Orleans; a Confederate soldier and later transferred as assistant surgeon to the medical corps; for two years surgeon to the Confederate Veteran Soldiers' Home; died in Touro Infirmary, May 5, a few days after an operation for appendicitis, aged 67.

Clarence Bentley Paul, M.D. Marion-Sims College of Medicine, St. Louis, 1893; a member of the Iowa State Medical Society; supreme medical director of the Homesteaders; and one of the founders of the Brotherhood of American Yeomen; died suddenly at his home in Des Moines, May 8, from heart disease, aged 48.

William D. Wells, M.D. Memphis Hospital Medical College, Memphis, Tenn., 1894; formerly of Gans, Okla.; a member of the American Medical Association; died in the Sebastian County Hospital, Fort Smith, Ark., May 2, from the effects of chloral, supposed to have been taken with suicidal intent.

William H. Shultz, M.D. Indiana Medical College, Indianapolis, 1871; a member of the Indiana State Medical Association; a veteran of the Civil War; formerly president of the local board of U. S. Pension Examining Surgeons of Lebanon; died at his home in that city, May 6, from influenza, aged 48.

William Stanbury Plotner, M.D. Western Pennsylvania Medical College, Pittsburgh, 1888; the first student to enroll in that institution and valedictorian of his class; a member of the Turtle Creek Valley Medical Society; died at his home in East Pittsburgh, Pa., May 8, from disease of the liver, aged 48.

John Jones Burroughs, M.D. New Orleans School of Medicine, 1860; Bellevue Hospital Medical College, New York City, 1875; Jefferson Medical College, Philadelphia, 1876; a surgeon in the Confederate Service during the Civil War; died at his home in Houston, Texas, May 3, aged 78.

Noyes B. Prentice, M.D. Starling Medical College, Columbus, Ohio, 1855; Western Reserve University, Cleveland, 1857; for two terms United States marshal; one of the oldest practitioners of Cleveland; died at his home in that city, May 1, from pneumonia, aged 80.

Paul A. Barrier, M.D. Long Island College Hospital, Brooklyn, 1860; a member of the American Medical Association; surgeon in the Confederate service during the Civil War; died at his home in Mount Pleasant, N. C., May 5, from cerebral hemorrhage, aged 76.

Benjamin A. Jaudon, M.D. Jefferson Medical College, Philadelphia, 1853; surgeon in the Confederate service during the Civil War; president of the Marion County (Mo.) Savings Bank; died suddenly at his home in Palmyra, April 30, aged 76.

Landon Spray Murray, M.D. University of Wooster, Cleveland, Ohio, 1868; of Medina, Ohio; a member of the American Medical Association; died at the home of his niece in Seville, Ohio, April 29, from acute cardiac dilatation, aged 69.

Benjamin J. Fulkerson, M.D. New York University, New York City, 1881; a member of the American Medical Association and the Tyrone Medical Club; died at his home in Tyrone, Pa., from nephritis, May 6, aged 54.

Henry Clay Lane, M.D. Western Pennsylvania Medical College, Pittsburgh, 1902; a member of the Turtle Creek Valley Medical Association; died at his home in East Pittsburgh, Pa., May 7, from heart disease, aged 32.

David W. Riggs, M.D. Jefferson Medical College, Philadelphia, 1861; a surgeon in the Federal service during the Civil War; of Northside, Pittsburg, Pa.; died in Rochester, Minn., from pneumonia, May 7, aged 75.

Frederick Augustus Cutter, M.D. Bellevue Hospital Medical College, New York City, 1865; McGill University, Montreal, 1873; of Sutton, Que.; died at the home of his son in Berkeley, Cal., May 8, aged 66.

William Henry Finn, M.D. Harvard Medical School, Boston, 1863; surgeon in the Navy during the Civil War; a member of the Philadelphia Historical Society; died at his home in Philadelphia, May 5, aged 74.

Carey William Howe, M.D. University of Buffalo, N. Y., 1860; assistant surgeon of the One Hundred and Sixteenth New York Volunteer Infantry during the Civil War; died at his home in Buffalo, May 7.

Edward S. Carr, M.D. Jefferson Medical College, Philadelphia, 1874; a member of the Tennessee State Medical Association; died at his home near Castalian Springs, May 7, from cerebral hemorrhage, aged 56.

Henry W. Bishoff, M.D. University of Pennsylvania, Philadelphia, 1866; a member of the Dauphin County Medical Society; died suddenly at his home in Halifax, Pa., February 1, from myocarditis, aged 72.

Christian M. Schulte, M.D. Washington University, Baltimore, 1876; at one time ward physician in the health department of Baltimore; died at his home in that city, May 5, from pneumonia, aged 58.

William Davis Tanner, M.D., a veteran of the Mexican War; who practiced in White county, Ill., from 1850 to 1870; died at his home in Denver, April 8, from senile debility, aged 85.

George H. Thrash, Jr., M.D. Chattanooga (Tenn.) Medical College, 1892; died at the home of his father in Hominy, N. C., May 3, from septicemia, due to an operation wound, aged 40.

Luther J. Cranfill, M.D. Fort Worth (Texas) University, 1903; of Loco, Okla.; a member of the Oklahoma State Medical Association; died on a train near Fort Worth, Texas, April 25, aged 50.

George W. Eager, M.D. College of Physicians and Surgeons, New York City, 1846; for twenty-four years postmaster of Montgomery, N. Y.; died at his home in that place, April 23, aged 84.

Henry R. Given, M.D. Rush Medical College, Chicago, 1871; a member of the Nebraska State Medical Association; died at his home in Wymore, April 18, from diabetes, aged 62.

Nathaniel M. Smith, M.D. College of Physicians and Surgeons, Keokuk, Iowa, 1881; died suddenly in his apartments in Marion, Kan., May 3, from heart disease, aged 58.

Elwyn Ashworth Holroyd, M.D. Rush Medical College, Chicago, 1879; died at his home in Chicago, May 13, from hemorrhage of the lungs, due to pulmonary abscess, aged 57.

Joel Eff Buckman, M.D. Barnes Medical College, St. Louis, 1904; of Modesto, Ill.; died at the home of his parents in Farmingdale, Ill., May 3, from tuberculosis, aged 30.

Marinda Emily Fullam, M.D. Northwestern University Woman's Medical School, Chicago, 1886; died at her home in Aurora, Ill., January 5, from paralysis, aged 68.

Velmore Huse, M.D. Baltimore Medical College, 1898; of New York City; died in the Austin Hospital, New York City, May 7, from appendicitis, aged 34.

O. W. Morris, M.D. Indiana Eclectic Medical College, Indianapolis, 1893; died at his home in Elwood, Ind., May 5, from cerebral hemorrhage.

Timothy Edward McOwen, M.D. Harvard Medical School, Boston, 1885; of Lowell, Mass.; died at St. John's Hospital in that city, May 5, aged 47.

John W. Megee, M.D. Beaumont Hospital Medical College, St. Louis, 1889; died at his home in Clarence, Mo., April 29, from tuberculosis, aged 53.

Robinson Peter Corbett (license, Ohio, 1896; years of practice); died at his home in St. Louisville, Ohio, from senile debility, May 8, aged 82.

Ephraim H. Harris, M.D. New York Medical College, New York City, 1866; died at his home in Grinnell, Iowa, May 5, from paralysis, aged 79.

James McGuffin, M.D. Electropathic Institute, Philadelphia, 1877; of Milwaukee; died at the Layton Home in that city, May 6, aged 80.

Charles C. Phillips, M.D. Philadelphia College of Medicine and Surgery, 1853; died at his home in Pitman, N. J., April 22.

Daniel Webster Durrett, M.D. University Medical College, Kansas City, Mo., 1900; of Pawnee, Okla.; died at the home of his brother near Emden, Mo., April 23, from tuberculosis, aged 38.

Henry Barnett, M.D. Eclectic College of Maine, Lewiston, 1887; died at his home in Lancaster, N. H., April 29, aged 52.

Medical Economics

THIS DEPARTMENT EMBODIES THE SUBJECTS OF ORGANIZATION, POSTGRADUATE WORK, CONTRACT PRACTICE, INSURANCE FEES, LEGISLATION, ETC.

The Medical Profession and Vital Statistics

The May number of the *Ohio State Medical Journal* states that J. J. Boone of Mt. Victory has been arrested for failure to comply with the vital statistics law, he having refused to report deaths because the law does not provide pay for such service. It is proposed to make this a test case to determine whether the state has a right to require compulsory service of professional men without providing compensation.

Commenting on the case, the Ohio editor says, "Every profession, whether law, journalism, education, medicine, the ministry, etc., primarily exists in the interests of the public. The organized effort of each one is directed to this end. Failing in this it would degenerate and fail of its own mission. The state, recognizing the functions of the various professions toward the people, enacts and enforces laws to conform to professional standard. Vital statistics stand in relation to the public good. The organized medical profession appreciates this fact and has been instrumental in securing the vital statistics law. All sanitary laws represent the progress of the medical profession. Professional standards are expressed in the language of state medicine. Medical licensure by the state is intended to safeguard public interests and imposes those conditions of qualifications and public service which the right to practice medicine implies. Men whose occupations stand in relation to the public health are required to conform to certain rules of conduct . . . laws are passed in the interest of the people and not especially for the medical profession. They are intended for the physician to obey. . . . It is a foregone conclusion that the courts will not grant special favors to physicians under the operations of the vital statistics act."

The only legal justification which can be found for the requirement by the state of a license on the part of a practicing physician is that the legally qualified physician occupies

the position of a quasi-public official and that in return for the performance of certain duties he is granted certain special privileges. It is necessary for the good of the community that carefully compiled statistics should be available regarding the causes of death. To be of any value such statistics must be based on reports from competent persons, that is from legally qualified and recognized physicians. The duty of making reports of births and deaths therefore is a part of the implied contract by which the physician holds a license from the state authorizing him to practice medicine. As every attorney who is admitted to the bar by the profession of his state is regarded, in a sense, as an officer of the state, so every legally qualified physician should be regarded, in a sanitary and hygienic sense, as a state health officer. The duty of reporting births and deaths is one of the most important of his obligations and should not for a moment be neglected nor should the state be expected to provide a nominal compensation for such service. If the physician were on the same plane as the grocer or dry-goods merchant, he could reasonably refuse to perform any service unless he were compensated therefor. The grocerman, however, does not receive any license from the state, neither does he ask the state to prevent any except legally qualified grocermen from engaging in business. When the medical profession assumes the position of a specially qualified and privileged class, it must recognize the duties and obligations of such a class as well as the advantages. The enforcement of the new Ohio law regulating vital statistics is of great importance at the present time.

POSTGRADUATE COURSE FOR COUNTY SOCIETIES

DR. JOHN H. BLACKBURN, DIRECTOR
BOWLING GREEN, KENTUCKY

[The Director will be glad to furnish further information and literature to any county society desiring to take up the course.]

Tenth Month—Fourth Weekly Meeting

ACUTE MASTOIDITIS

Causes, general and local, symptoms and physical signs, prognosis, abortive treatment. Operative treatment, indications, technic.

SUPERIOSTEAL ABSCESS IN ACUTE MASTOIDITIS.—Diagnosis and treatment.

ACUTE MASTOIDITIS IN INFANTS.—Differences in temporal bone, in symptoms; treatment.

CHRONIC MASTOIDITIS

Pathology, symptoms. Radical mastoid operation, indications, technic, dangers. Intracranial complications, frequency, mortality. Sinus phlebitis and sinus thrombosis, pathology, symptoms, treatment. Otitis brain abscess, symptoms, diagnosis. Cerebellar abscess, symptoms, diagnosis. Infective meningitis, pathology, diagnosis, prognosis.

CHRONIC NON-SUPPURATIVE OTITIS MEDIA

Causes, pathology, diagnosis. Palliative and surgical treatment.

OTOSCLEROSIS.—Causes, diagnosis, treatment.

LABYRINTHINE DISEASES.—Causes, diagnosis

MONTHLY MEETING

The Early Diagnosis and Treatment of Acute Catarrhal and Purulent Otitis Media.

The Relation of Nasopharyngeal Diseases and Obstructions to Diseases of the Ear.

The Symptomatology and Diagnosis of Acute Mastoiditis.

END OF SECOND YEAR COURSE

The program for the last meeting of the tenth month as given above, concludes the outline of the second year of the Postgraduate Study Course. The publication of the third year outline will begin in September.

Society Proceedings

COMING MEETINGS

AMERICAN MEDICAL ASSOCIATION, ATLANTIC CITY, JUNE 8-11.

American Academy of Medicine, Atlantic City, June 5-7.
Am. Assn. of Genito-Urinary Surgeons, Pocono, Pa., May 31-June 1.
Am. Assn. of Med. Milk Commissions, Atlantic City, June 7.
Am. Climatological Association, Fortress Monroe, Va., June 4-5.
American Dermatological Association, Philadelphia, June 3-5.
Am. Gastro-Enterological Association, Atlantic City, June 7-8.

Wisconsin State Medical Society, Madison, June 30-July 2.

LOUISIANA STATE MEDICAL SOCIETY

Thirtieth Annual Meeting, held at New Orleans, May 4-6, 1909

The President, Dr. E. DENEGRÉ MARTIN, in the Chair

Election of Officers

The officers elected were named in THE JOURNAL, May 15.

Contribution to Carroll Fund

A resolution was adopted that \$150 be appropriated toward the fund for the relief of the widow of Major Carroll.

Prophylactic Serotherapy and the Theory of Anaphylaxis

DR. I. I. LEMANN, New Orleans: While anaphylaxis has been widely discussed during the past three years by workers in the field of immunity, it has received comparatively little attention in general societies and medical journals, this paper presents a brief summary of the literature and I ask: What shall be our attitude in regard to prophylactic injections of serum in the light of probable subsequent anaphylactic reactions? An experience which I had in January, 1907, illustrates one phase of the anaphylactic reaction. The patient, a girl of thirteen, frequently had sore throat, and on many of these occasions the attacks suggested diphtheria. During one of them, in November, 1903, she was given an injection of diphtheria antitoxin, but a swab culture taken at the time proved negative. At the time there were no symptoms of serum disease. In the last days of December, 1906, she had another of her customary attacks and the same thing was done; again the culture was negative. Twenty-four hours after the injection she developed a general urticaria, and the pulse became abnormally slow, although the temperature remained about 101 F. During the next twenty-four hours the pulse was as slow as 40 a minute. For several days the bradycardia continued and was gradually substituted by a tachycardia, which reached 120; this was associated with marked irregularity and intermission. There were no murmurs and there was no enlargement of the heart. This tachycardia continued for a year, while the irregularity of the cardiac action as manifested by undue hastening of the pulse on slight exertion continued for eighteen months. While we must insist on serum inoculations as a therapeutic measure of the highest value, how must we look on prophylactic injections in the light of possible subsequent anaphylaxis? I confess that after my experience I have given up the old rule of injecting antitoxin in doubtful cases at the time of taking the swab culture and have awaited the result of the bacteriologic examination. In this way, I have avoided, I think, unnecessary sensitizings and hence unnecessary risk in case of future urgent need of the employment of serum. About prophylactic injections I am inclined to feel the same way.

DISCUSSION

Dr. J. T. HALSEY, New Orleans: I have had two experiences similar to that of Dr. Lemann, and the lesson I have drawn is to avoid unnecessary antitoxin injections.

Dr. C. C. Bass, New Orleans: Admitting that anaphylaxis exists, we must not lay too much stress on it, or we will do more harm than good. When it is possible to make a culture in a suspected case of diphtheria, it is probable that we should not administer serum until a diagnosis is made. As a prophylactic measure we will probably in the future use bacterial vaccines.

DR. L. G. LEBEUF, New Orleans: I think some work ought to be done to determine which patients may receive injections with safety and which may not. Is any work being done along that line?

DR. J. I. LEMANN: The remarks I made do not apply to the therapeutic use of the serum. Klemperer has made a suggestion that we could determine whether or not it would be safe to give serum to a given individual by taking a small amount of blood from that individual and injecting it into a guinea-pig and then injecting the guinea-pig with horse serum also. If the guinea-pig reacts anaphylactically, it is unsafe to give the patient horse serum. It is plain, however, that this is not practical.

Treatment of Tuberculosis at Covington Sanatorium

DR. WALLACE J. DUREL, New Orleans: This report includes cases treated from 1905 to 1907. In all, 59 patients were treated. Of these, 2 were in the first clinical stage; 15 in the second; 21 in the third; 21 in the fourth. In 7 cases there was laryngeal involvement, 4 of the cases ending in recovery, and 3 in no improvement. In 11 cases there were stomach or digestive disorders, 4 ending fatally. Two patients suffered with joint tuberculosis; both recovered. The great percentage of the patients reported here as apparently cured had already followed the climatic treatment, without any benefit, before undergoing the hygienic-dietetic treatment. Most of the individuals were given tuberculin and creosote. The total percentage of results was as follows: First clinical stage, 100 per cent. apparent cure or complete recovery; second clinical stage, 100 per cent. apparent cure or complete recovery; third clinical stage, 57.1 per cent. apparent cure or complete recovery, 23.8 per cent. disease arrested, 19.1 improved, no mortality; fourth clinical stage, 19.1 per cent. disease arrested, 28.5 per cent. improved, 38.1 per cent. mortality. These statistics, while not large, should convince physicians that the cure of tuberculosis is not entirely dependent on climate.

(To be continued)

OHIO STATE MEDICAL ASSOCIATION

Sixty-fourth Annual Meeting, held at Cincinnati, May 5-7, 1909

President's Address: History of the Association

DR. D. R. SILVER, Xenia: The history of the organization may be divided into four periods, the first extending from 1812, when just five delegates were present. These men made a winter journey of more than 100 miles on horseback over the corduroy roads of that time, nearly a century ago. In 1827, fifteen years later, a convention was held at Columbus, with Dr. Wooley, of Cincinnati, as president, at which time a plan and constitution for a state medical society was adopted, the first session of which was to convene in 1829. However, the organization seems never to have proceeded beyond the convention form, and was operated under the old district medical law, which was repealed in 1833. The second period of medical history dates from January, 1835, when Dr. William Aul, of Columbus, issued a circular letter to all regular and scientific medical practitioners who were desirous to advance the honor and dignity of the profession, to meet in convention. They did meet, and Dr. Daniel Drake was one of the leading spirits. He gave an address urging the establishment of a school for the instruction of the blind. Under this system medical conventions continued to be held until May, 1846, when the Ohio State Medical Society was organized at the Neil House in Columbus, and the enrollment of membership numbered 25. Thus commenced the third

period of medical history in Ohio. The fourth period began with the reorganization in 1902, when the membership was about 1,000. The work of Dr. McCormack, in Ohio, has contributed not a little to a more perfect organization of the profession and a great deal to the education of the people of the state. The senatorial candidacy of Dr. C. A. L. Reed can not fail to have a far-reaching influence in shaping future legislation. Optometry is the most plausible of any of the pretensions of quackery, and to oppose this form of charlatanry I recommend that the component societies provide for the reading of papers in the annual programs on the subject of refraction and other anomalies of vision. The Ohio Commission for the Blind, which was inaugurated at the instance of the American Medical Association, is doing good work. I also recommend the establishment of tuberculous sanatoria, and that the medical profession take an active interest in directing the laity, so that there may be no mistake there in political influence. Vasectomy should be performed on habitual criminals because the propagation of the criminal classes is said to be more than twice as great as the general population. In the election of delegates to the American Medical Association I recommend that the secretary of the state society and the chairman of the legislative committee be ex-officio delegates to the parent society, and that the other four delegates, to which we are entitled, be elected for a period of four years instead of two, for the purpose of obtaining greater influence in the deliberations of the national association.

Report of Committee on Public Policy and Legislation

The optometry bill, providing for a state examining and licensing board, was introduced in the senate, but not reported out of committee. A bill to give authority to boards of education for the medical inspection of public school children was enacted. An attempt to introduce a bill looking to the creation of a state examining board for nurses was frustrated. A suggestion that the house of delegates adopt resolutions placing the association in cooperation with the temperance movement in Ohio, by urging all members to comply with the intent of prohibition laws in exempting alcoholic preparations when prescribed for medicinal purposes, was duly carried out. The committee reiterated the defensive attitude necessary to be taken by the association in order to protect the Medical Practice Act against the invasion of cults and classes who are constantly seeking recognition by the state for the favor of practicing medicine in some of its branches without proper qualification before the state board.

Reports of Officers

The treasurer reported that the amount received last year from dues was \$3,962.00, representing so many members of the association. The amount received from subscription, \$5.00; from advertising, \$3,214.00, making a total of \$7,355.00, of which \$7,226.00 was paid out, leaving a balance on hand of \$129.00.

Election of Officers

The officers elected were named in THE JOURNAL, May 15.

Multiple Myeloma

DR. GEORGE F. ZINNINGER, Canton: Judged by their histopathologic structure, in that they have a definite specific cell and a connective tissue and blood vessel stroma, together with the fact that they show distinct evidence of invasive growth by breaking through bony walls and infiltrating adjacent structures, one can hardly hesitate to regard these tumors as true neoplastic growths. If on the other hand the multiple tumors are not metastases into a single system, but tumors all of multiple inception, this seems to lend support to the view that they are due to some generalized disease most probably of an infectious etiology. These tumors always arise in the bone marrow, proliferating, and producing erosions of the bones in which they arise. In their histopathologic structure similarity is to be noted in the description of the various authors reporting the cases. They all speak of a tumor made up of a delicate stroma of connective tissue; in the meshes of the stroma are packed cells which may be round,

but more often are oval or pear-shaped, having no cell wall, bearing a rather large single or multiple nucleus usually eccentrically placed and in most of them nuclei are to be found. The tumors are very vascular; the larger and smaller blood vessels ramify in the sparse connective tissue stroma. The vessels are thin-walled, and the tumor cells are in intimate relationship with the vessels. Clinically, there is constant pain over definite areas of bone having a cancellous structure, the bone developing a bulging swelling, the appearance later of definite soft tumor masses. The patient shows some emaciation, growing pallor, anemia and weakness, all of which are strongly suggestive of multiple myeloma.

Aspects of Angina Pectoris

DR. FRANK WINDERS, Columbus: A study of this subject may well be preceded by the statement that angina pectoris is not a distinct disease, but rather a symptom group, the etiology and pathology of which must be determined for each individual case. I accept the classification of Nothnagel, who distinguishes angina pectoris major, in which there are definite anatomic changes in the heart or its vessels, from angina pectoris minor, in which no such changes can be demonstrated. So-called minor cases are not infrequently as grave in their prognosis as the major cases. Cases which at autopsy show lesions of the heart or its vessels present either (a) disease at the first portion of the aorta or at the aortic valve, which causes interference with the entrance of blood into the coronary arteries; or (b) disease of the coronary arteries. The association of attacks of angina and disturbance of digestion has long been recognized, but it remained for Russell to give a plausible explanation of this relation. This author directs attention to the normal arterial abdominal reflex and its exaggeration as an important factor among the causes of angina pectoris. An additional factor has to do with the increase of blood pressure, following the ingestion of heavy foods and stimulating drinks and is the presence in the blood itself of products of digestion which act as irritants to the arterial coats, thereby exciting them to contraction. A continuation of these influences results in a continued arterial contraction and this in turn in a compensatory thickening of the arterial walls. Cardiac embarrassment results from the foregoing causes. A general arterial hypertonus produces a narrowing of the lumen of the vessels, which in turn causes an increase in blood pressure, and thus an increased burden is placed on the heart in its efforts to empty the left ventricle.

MISSISSIPPI STATE MEDICAL SOCIETY

Forty-second Annual Meeting, held at Jackson, April 13, 1909

(Continued from page 1610)

The Hypodermatic Use of Quinin in Severe Malarial Infection

DR. B. H. BOOTH, Drew, advocated the hypodermatic use of quinin, especially in treating children. It was more effective by this manner of administration and by so using it we avoided irritating the stomach. The administration by needle reduced the amount and number of doses and was really less objectionable than the discomfort produced by the nauseous taste of the drug. The danger of abscess formation was not great when proper care in administering and proper asepsis were observed. Any soluble salt might be used, his preference being the bimuriate.

DISCUSSION

DR. GLASS, Coahoma: In administering quinin hypodermically, too small a syringe is generally used. I have found in using the ordinary hypodermic syringe that the solution was too concentrated, too irritating; therefore, I use my antitoxin syringe, dissolving the quinin in a saline solution. When given in this way one can usually note the effect of the quinin in about forty minutes. It is important that the solution be sufficiently diluted.

DR. E. H. MARTIN, Hot Springs, Ark.: When it is necessary to administer quinin hypodermically, it should be dis-

solved in a sufficient quantity, preferably a saline solution, to insure absorption. Given in this way, there is little danger of abscesses.

DR. G. H. McNEILL, Newton: A sufficiently diluted solution can be administered with the small syringe, by detaching the bulb and refilling it as often as desired, and this can be done with only one insertion of the needle. I say this for the benefit of the physician who does not possess a large syringe.

DR. DULANEY: I am much gratified to note that the profession is getting back to the use of quinin. In administering this drug hypodermically, I dissolve 5 grains of quinin in 30 drops of water; I have no trouble with abscesses, and usually obtain good results.

DR. H. CHRISTMAS, Tchula: A physician of many years' practice was sent for in a case of hematuria. When he arrived he questioned the young physician in attendance as to what he had done for the man. The doctor replied that he had blistered him, given calomel and almost a bottle of quinin. The older physician then suggested giving the man a rest; giving him a hypodermic of atropin and something to eat, and see what the effect would be. The next morning the man was much better, and eventually recovered. He then told the young doctor the man was dying of too much doctor, and not from the disease.

DR. ASHLEY: Have any patients complained of intense pain when given quinin hypodermically? I was given quinin hypodermically and my suffering was almost unbearable. The first two injections were not so painful, but the others caused intense pain. It did not cause abscesses, only the usual knot, which I still have. The quinin was given in very diluted form, and with good effect as to the disease.

DR. COOK, Forest: Possibly the bad effects resulting from giving quinin hypodermically are caused by giving it under the skin; if injected deep into the muscles there would be no danger of abscesses. I had a patient who could not take quinin by mouth without producing a rash. She was very ill, and all other remedies had failed. I gave a diluted solution of quinin bismuriate hypodermically, putting the needle deep into the muscles. No bad effects followed, and the patient recovered.

DR. H. L. SUTHERLAND, Rosedale: I suppose that all physicians are of the opinion that quinin is the only safe remedy in malaria. The main thing, however, is to determine whether the condition is active malaria, or anemia secondary to malaria. If repeated examination of the blood does not reveal the parasite, I see no use in giving quinin, but if the examination reveals the parasite, I always give quinin. In giving it hypodermically, if in a weak solution, and the needle is put deep into the muscles, there is little danger of abscesses.

DR. B. H. BOOTH: I hope that I made it clear in the paper that if care is taken not to strike a vein there is little or no pain in the hypodermic administration of quinin.

Puerperal Eclampsia

DR. L. D. HARRISON, Clarksdale, advocated bleeding in eclampsia. The preventive treatment, the care of the patient during pregnancy, must not be neglected but when brought face to face with the condition no time is to be lost and blood should be taken, the idea being to bleed for effect and not for quantity.

DISCUSSION

DR. M. ALEXANDER, Tunica: In the days of bloodletting, this disease was looked on with dread by all practicing physicians. I can not understand why a physician should go back to the dark ages for a remedy when there is such a remedy at hand as veratrum, which in my opinion is almost specific in puerperal eclampsia, eliminating urea, which to a great extent has poisoned the system, and relieving the pressure on the nervous system.

DR. JONES: I believe in the old foggy idea, if you have a good thing, stick to it. In puerperal convulsions I consider

blood letting a safe remedy. In cases of puerperal eclampsia what is needed is complete relaxation both inside and outside.

DR. M. C. ELLIS, Senatobia: When I find that I can not control convulsions with veratrum, and the pulse was still bounding, I bleed, and bleed for effect—bleed until the pulse is slower.

DR. A. E. KENNEDY, Magee: I believe in calomel in puerperal eclampsia, and plenty of it. In a case that I had some years ago, I gave 60 grs. of calomel, followed by an ounce of castor oil. The woman recovered.

DR. P. BUTLER, Little Springs: I treated the first cases of puerperal eclampsia that I had by bleeding, but in my hands bleeding was not satisfactory. Since I began to use veratrum, followed by bichlorid of mercury, I have not lost a patient with puerperal eclampsia.

DR. R. M. DONALD, Hattiesburg: In puerperal eclampsia I give large doses of veratrum, repeated if necessary, and just as soon as I can get the patient to take it, I give calomel in large doses.

DR. L. D. HARRISON: Dr. Alexander stated that he could not remember so far back when this ancient remedy of bloodletting was resorted to, but I can refer to authorities as late as 1906-1908 who advocate bloodletting in puerperal eclampsia. Veratrum, I contend, weakens the heart action, and does not aid elimination. I have never seen a case of puerperal eclampsia that was not relieved by bloodletting. I have seen patients die from all the treatments named, but I have never yet seen one die from bloodletting. The other remedies are not quick enough in their effect.

Hygiene and Prophylaxis in the Care of Children

DR. O. N. ARRINGTON, Brookhaven, entered a plea for greater care in the handling of children. Education of the laity along these lines is sadly needed, most deaths among children being from preventable conditions.

DISCUSSION

DR. ROSAMOND, Memphis, Tenn.: Too much can not be said about the necessity of the baby being given its mother's milk and that mother who can nurse her baby and won't, is morally responsible for that child's life. Another subject of grave importance is the problem of the negro nurse girl. The physician can not make too great an effort to instruct the mother along this line. The nurse girl carries the little baby into all manner of filthy dens, and the mother is sitting quietly at home, either ignorant or indifferent as to where her child is being taken. It is in these places that the baby contracts all manner of contagious and infectious diseases.

DR. ROSA WISS, Meridian: The physician should impress on the mother the importance of giving the baby water. Babies do not want it at first, but they soon acquire a taste for it. The baby who is given water is usually a healthy baby.

DR. B. L. CULLEY, Jackson: If you begin right with the baby, it is not hard to keep right, and the right way to start the baby off is at its mother's breast. I do not think that a physician should be too hasty in cutting the cord, as the baby should be allowed to get a good supply of blood to start life with. Another important point is to impress on the mother the baby's need of water. So many mothers are afraid to give the baby water, and have to be told to do this from the very beginning of the child's life. It will frequently stop a colicky baby from crying when nothing else will.

DR. COOK, Hattiesburg: When the mother has a superabundance of milk, more than the child can digest, it will suffer with colic, and will vomit up the milk constantly. I think a restriction should be made as to the quantity of milk taken.

DR. ELLIS: In cases in which the mother has a superabundance of milk, but the milk is blue, I give potassium, which lessens the quantity of milk, but increases its richness.

DR. DAVIS: When the mother gives too much milk, I find that using only one breast acts admirably. Very often mothers give more milk from one breast, and in those cases I would let the mother dry the other breast.

MEDICAL AND CHIRURGICAL FACULTY OF MARYLAND

One Hundred and Eleventh Annual Meeting, held in Baltimore,
May 11-15, 1909

Dedication of New Building

With three days of perfect May weather the Medical and Chirurgical Faculty of Maryland held its one hundred and eleventh annual meeting and celebrated the completion and occupation of its fine new library building, May 13, 14 and 15. A picture and description of the building appear in this issue of THE JOURNAL, page 1679.

The presentation address was made by Dr. Edward N. Brush, Baltimore, chairman of the building committee. "This building belongs, it is true, to the medical profession, but solely as a means of helping the citizens of the state. Here is housed a library which is in constant demand, not alone and not by any means in its broadest intention and use, for the benefit of the medical men who resort to it, but for your benefit, men and women of Maryland, and for the benefit of your families."

Felicitating addresses were also made by Dr. Abraham Jacobi, representing the New York Academy of Medicine; Dr. James Tyson, representing the College of Physicians of Philadelphia, and Dr. John W. Farlow, of the Boston Medical Library Association.

The acceptance of the building in behalf of the society was by the president, Dr. Brice W. Goldsborough, who said: "We have looked forward to this day for many months with happy anticipations, and we are not disappointed. The erection of this building has been the inspiration of our lives. It will promote harmony. It will elevate the profession out of selfishness. It will aid in the development of our fellow-men. It will establish good-fellowship. I voice the unanimous sentiment of the society when I testify to the untiring zeal, energy and devotion of the building committee." Dr. Goldsborough gave an interesting summary of the past history of the society and particularly of its recent work and made a number of suggestions for increasing its efficiency.

Legacies and Gifts

Dr. Edward N. Brush, Baltimore, chairman of the building committee, announced that \$20,000 had been left to the faculty by the will of a member whose name he was not permitted to give. Dr. William Osler, Oxford, Eng., announced a gift to the library of the first edition of Vesalius, which he purchased recently in Rome. An interesting even of the last evening of the meeting was the presentation of a portrait of Dr. William H. Stokes, formerly superintendent of Mount Hope Retreat, by Dr. Henry M. Hurd.

The Old and the New

Dr. William Osler, Oxford, Eng., delivered an address with the above title in Osler Hall. Overhanging him as he spoke was his full-length portrait in oil, the gift of his friends, and the only ornament of the room. The address will appear in full in THE JOURNAL.

Reports of Committees and Officials

The Committee on Public Instruction reported that twelve jubilee lectures had been delivered during the winter by Drs. G. M. Linthicum, L. F. Barker, J. M. T. Finney, J. C. Bloodgood, W. T. Watson, Harry Friedenwald, H. O. Reik, R. T. Abercrombie, B. Holly Smith, W. P. Spratling, Misses M. E. Lent and E. N. La Motte. The lectures were delivered at the Baltimore Medical College Building, and such topics as "Hygiene of the Mouth and Eye," "Insects in Disease," "Nursing," "Physical Development," "Non-Drug Treatment," "Care of the Ear," "State Cure of Epileptics," etc., were treated. Other lectures have been given before societies, mothers' meetings, etc. In addition to this, a series of weekly articles on similar topics have appeared in the newspapers. Lectures on tuberculosis and other subjects have also been delivered in the counties. The aid of the newspapers was also sought in the effort to reach the public and weekly "Health Bulletins" were published in the Sunday papers from June 14, 1908, to the present time. These articles dealt with their subjects in a simple, popular manner and were anonymous. They were favorably received and highly appreciated by the public and also by the newspapers and have brought about kindly rela-

tions with the latter, which have not always heretofore existed. The faculty has not been called on for one cent for this work. The small amount of \$15 needed being contributed by the members of the committee. The committee is proud of the fact that it instituted the first instance of such work in the country and that essentially the same plan has been adopted by the American Medical Association.

The report of the Library Committee and Librarian showed that there are now 17,533 books and 176 current journals on file. There were 4,353 readers, and 1,541 books were borrowed for home use. Portraits have been acquired of Drs. I. E. Atkinson, G. J. Preston, Russell Murdock, Moreau Forrest and a print of Rembrandt's Anatomy. Among gifts are Dr. A. D. Atkinson, 183 books; Dr. H. B. Jacobs, 77; Dr. William Osler, 22; Miss Miller, 135; Dr. Charles O'Donovan, 24; etc. Dr. Jacobs gave complete sets of the *Annales de l'Institut Pasteur*, and of the *Bulletin et Mémoire de l'Académie Impériale de Médecine*. Dr. Osler gave a first edition of Vesalius. The library will be open hereafter with a trained attendant on hand till 10 p. m.

The Committee on Sanitary and Moral Prophylaxis reported that a woman had been engaged in instructing women and children along the lines of sex hygiene. Much literature has been distributed and lectures have also been given by members of the society in the counties. Arrangements have been made to give annual lectures at the medical schools on prophylaxis of venereal disease, inculcating that the prostitute is really nothing more nor less than a focus of infection. To ascertain the sentiment regarding sexual necessity 1,014 letters were sent out to physicians and 615 replies were received. There were 484 who did not believe that health was affected by entire abstinence, while 105 asserted the contrary, and 26 were non-committal; indicating that one doctor in every ten in this state is sanctioning the use of prostitutes by unmarried men, a striking result as coming from a body of scientific men and one which can not fail to increase the prevalence of venereal disease. To carry on the work \$3,043.78 has been raised by dues and contributions, of which \$2,803.31 has been disbursed in salaries and running expenses. The Medical Society of Social Hygiene co-operates with the committee. The committee recommends that teaching on sex hygiene be made a part of the medical course in the schools and that action be taken by the society on the question of vasectomy in criminals, insane and imbecile.

The secretary reported an unusually successful year both as to finances and organization. The county societies are in an active and healthy condition, except that of St. Mary's County. The Garrett and Allegany County societies have united, owing to the difficulty in keeping up the first named.

The trustees reported that the property of the faculty on Hamilton Terrace had been sold in fee for \$9,000. The building and site cost about \$90,000. The present debt is about \$32,000.

The Committee on Lay Press reported that cordial relations had been established with the papers, which could not fail to benefit the profession and the public.

Reciprocity

The Board of Medical Examiners reported that Maryland is now in reciprocal relations with Maine, New Hampshire, Vermont, Virginia, West Virginia, District of Columbia, Georgia, South Carolina, Texas, Kentucky, Missouri, Kansas, Nebraska, Oklahoma, Iowa, Minnesota, Michigan, Wisconsin, Illinois, Indiana and Ohio. In a number of states the law makes no provision for recognition of licenses of other states and the Maryland law forbids recognition of licenses of such states. New Jersey has severed its reciprocal relationship on account of differences of preliminary requirements. Delaware and Ohio have also raised their requirements. Accordingly, the Medical Colleges of Baltimore have responded to the demands that those entering on the study of medicine shall be possessed of the preliminary education regarded as essential by those representing the best sentiment on this subject, and the Boards of Medical Examiners of Maryland now interpret the wording of the law, "a competent common school education," to mean "a completed high school education" and no

applicant is admitted for examination to either board who can not give proof of such requirements. The board declares in unmistakable terms its intention to follow and punish the illegal practitioner of medicine, and appended to the report are the results of thirty-two prosecutions of offenders made during the year. At present it does not seem feasible to conduct examinations in laboratories or at the bedside, and the method in vogue will probably continue.

Officers Elected

The following are the officers elected for the ensuing year: President, G. Milton Linthicum, Baltimore; vice-presidents, Drs. Philip Briscoe, Mutual, and Compton Riely and Arthur P. Herring, Baltimore; secretary, Dr. John Ruhrah, Baltimore; treasurer, Dr. William S. Gardner, Baltimore; trustee, Dr. Daniel E. Stone, Mount Pleasant; members State Board of Medical Examiners, Drs. Brice W. Goldsborough, Cambridge, and Louis B. Henkel, Jr., Annapolis; councilors, Drs. Guy Steele, Cambridge; Arthur Hawkins, Cumberland, and David Street, Baltimore; delegate to the American Medical Association, Dr. Lewellys F. Barker, Baltimore; alternate, Dr. Samuel T. Earle, Baltimore; committee on scientific work and arrangement, Drs. Joseph Chatard, Arthur M. Shipley and Isaac R. Pels, Baltimore; committee on public policy and legislation, Drs. C. Hampson Jones, and John D. Blake, Baltimore, and W. Frank Hines, Chestertown; library committee, Drs. J. Whitridge Williams, H. Barton Jacobs, Harvey W. Cushing, Gordon Wilson, and Carey B. Gamble, Baltimore; memorial committee, Drs. Joseph T. Smith, Baltimore; Walton Bolgiano and George H. Cairnes, Baltimore; William C. Stone, Ellicott City, and Thomas H. Brayshaw, Glen Burnie; committee on sanitary and moral prophylaxis, Drs. Donald R. Hooker, Lillian Welsh, Hugh H. Young, O. Edward Janney, and Andrew H. Whitridge, Baltimore; committee on tuberculosis, Drs. Jacob H. Pleasants, John W. Chambers, Richard B. Norment, and Sylvan Rosenheim, Baltimore, and Philip L. Travers, Easton; committee on pure food law, Drs. Nathan R. Gorter, Samuel J. Fort, and Edward L. Whitney, Baltimore, and committee on funds for widows and orphans, Drs. Eugene F. Cordell, Theodore E. Cook and G. A. Christian Deetjen, Baltimore; Richard W. Trapnell, Point of Rocks, and Jacob L. Noble, Preston.

(To be continued)

Medical Education and State Boards of Registration

STATE BOARD STATISTICS FOR 1908

The Annual Presentation of the Results of State Board Examinations with Analyses and Deductions

On pages 1698 to 1713 will be found four tables, A, B, C and D, giving in detail the results of the various state medical license examinations held during 1908. Reports from Oklahoma were received for only one of the two examinations held; otherwise our returns are complete.

These tables have been arranged so that reading from left to right gives the results by colleges, showing how many graduates appeared for examination in each state and whether they passed or failed, as well as the total number examined during the year, the number who passed, the number who failed, the percentage of failure and the number of states in which graduates of each school appeared for examination. Reading from above downward gives the results by states, showing the number registered and rejected from each college, the total number examined, the total number registered, the total number rejected and the percentage of rejections. The fact that the majority of graduates take the license examination in the state in which the college is located is shown by the dark diagonal zone, made by the grouping of figures, passing from the left upper to the right lower corner of each table. These tables are worthy of much careful study and many important deductions are possible.

GRADUATES OF ALL YEARS, EXAMINED IN 1908

Table A shows the results for all candidates who took examinations in 1908 regardless of the years in which they graduated. This shows that altogether 7,770 were examined last year, as compared with 7,271 in 1907 and 8,035 in 1906. Of those examined, 21.7 per cent. failed, as compared with 21.3 in 1907, 20.7 per cent. in 1906 and 20.8 per cent. in 1905.

There were 137 of the medical colleges in the United States which had graduates examined. Foreign graduates were examined in 31 states, the total number being 160. The largest number examined in any state was 85, in New York, doubtless because that state has the leading port of immigration. Graduates of Canadian schools were examined in 31 states, more appearing naturally in the border line states.

GRADUATES OF 1908 EXAMINED DURING 1908

Table B gives the results for the graduates of 1908 who were examined during the year by state boards and shows that 4,388 or 56.5 per cent. of all candidates examined during the year graduated in 1908. Educational statistics show that the medical colleges of the United States graduated 4,741 students last year; therefore about 90 per cent. of all 1908 graduates took examinations for license during the year. In some of the states graduates in medicine are allowed to serve their hospital internships without first becoming licensed practitioners, which doubtless accounts for some of the remaining 10 per cent. Of those examined 607 or 13.8 per cent. failed. An analysis of this table shows that of all the 1908 graduates examined 2,823 or 64.4 per cent. were examined in the states in which the colleges from which they graduated were located. This shows that states which sanction low grade colleges are not only responsible for the ill-prepared output of such colleges, but are themselves the recipients of the greater portion of such output.

RECENT GRADUATES EXAMINED DURING 1908

Table C gives the results for graduates of 1903 to 1908 inclusive which were examined during 1908. It includes, therefore, the figures given in Table B. This table is particularly important since it deals with recent graduates and is, therefore, the fairest basis for comparison between colleges. Any classifications of medical colleges from the standpoint of failures at state board examinations should be based on this table. Of all candidates examined in 1908, 6,477 or 83.3 per cent. were recent graduates, and of this number 17.8 per cent. failed, as compared with 21.7 per cent. for all candidates.

OLD PRACTITIONERS EXAMINED IN 1908

Table D is interesting because it shows the results for candidates who graduated in 1902 or previously. The total number examined was 796 or 10.3 per cent. of all candidates examined, as compared with 675 in 1907 and 793 in 1906. This year, of those examined, 251 or 31.5 per cent. failed, as compared with 17.8 per cent. of failures for recent graduates. This total should decrease each year as advances are made in reciprocity. As a rule, the states examining the largest numbers are those which do not reciprocate with other states. A comparison with Table X will be of interest in this connection.

UNDERGRADUATES EXAMINED DURING 1908

Line 141 of Table A shows the number of undergraduates examined in nine different states during 1908. Altogether 494 were examined, as compared with 674 in 1907 and 703 in 1904. The states in which undergraduates appeared, arranged in the order of the number examined, were: Mississippi, 182; Arkansas, 130; Tennessee, 100; Massachusetts, 37; Alabama, 36; Rhode Island, 6, and 1 each in Kansas, North Carolina and Virginia. Legislation requiring graduation of all applicants has since been secured in Alabama, Arkansas and Rhode Island which will greatly reduce the figures in future reports. Of the 494 undergraduates examined, 281 or 56.8 per cent. failed.

COMPARISON WITH PREVIOUS YEARS

A study of the totals and percentages as compared with previous years is of interest. The totals of those examined show a decrease from last year, while the percentage of failures is somewhat higher.

COMPARISON WITH PREVIOUS YEARS (TABLES A, C AND D).

Year.	Total Examined.	Examined— Passed.	Examined— Failed.	Percentage Failed.	Recent Grads. Examined.	Percentage Failed.	Older Pract. Examined.	Percentage Failed.	Non-Grads. Examined.	Percentage Failed.	Registr'd With- out Written Examination.	Total Registered.

1908	7770	6384	1386	21.7	6477	17.8	796	31.5	491	56.8	1276	7360

Other deductions from the larger tables have been made and are pre-sented in Tables E to N which are worthy of careful study.

STUDY OF COLLEGES BY STATE GROUPS

Table E is based on the first four large tables and gives data regarding the group of colleges located in each state. It shows what states are furnishing the largest numbers of physicians and the failure percentages show what kind of training these colleges are furnishing, so far as may be judged from the fail-ures of their graduates before state boards. By comparing the

This table gives data relating to the group of colleges in each state. For example, it shows that of all the medical schools in New York 571 graduates of various years were examined by state boards during 1908, of which number 3.2 per cent. failed. Of the 536 who graduated in recent years, however (1903 to 1908 inclusive), only 2.1 per cent. failed, while of the 35 who graduated previous to 1903, 20 per cent. failed.

The fifth column gives the rank of each state group of colleges according to the number of applicants. The Illinois group of colleges leads, having 843 graduates examined by state boards during 1908, followed by Pennsylvania with 700, New York with 571, Tennessee with 569 and Maryland with 567.

The sixth column gives the rank of each state group of colleges according to the success of the graduates at state board examinations. It is interesting to compare the figures of these two last columns. While the Illinois group ranks first according to the number examined it ranks thirteenth in the success of its gradu-ates at examinations. While Pennsylvania ranks second as to the number examined, it ranks fifth as to the success of the grad-uates.

percentages of the first column with the other columns it can be seen whether there has been any reduction in failures in recent years. Of the 33 states having medical colleges, 18 fur-nished 100 or more candidates examined. Of these 18 groups of colleges, only 4 had failure percentages of 10 per cent.; 8 had failure percentages between 10 and 20, and 6 had over 20 per cent. of failures. The highest failure percentage was ob-tained by the Mississippi group. Of the states having 100 or more examined, however, the highest failure percentage was obtained by the Tennessee group, which had 35.7, followed by the Kentucky group, with 33.8 per cent. Other deductions are given with the table.

STUDY OF LARGER COLLEGES

Table F is also based on the first four tables and gives the results of state board examinations as they affect the 45 largest medical colleges. Although these schools represent less than one-third of all medical colleges in the United States, they furnish 4,421 or about 60 per cent. of all the candidates for license. Of these colleges, even with the graduates of 1908, many show extremely high failure percentages. Of the 19 col-leges having 100 or more examined, five stand out prominently with failure percentages of over 30 per cent.

Altogether for these schools 686 or 15.5 per cent. failed, as compared with 20.8 per cent. of failure for the 2,070 candidates from the 92 colleges having less than 50 each examined.

COMPARISON WITH PREVIOUS YEARS (FROM TABLE F).

Year.	Colleges Repre- sented.	Total Examined.	Per Cent. Failed.	Colleges, 100 or More Examined.	Total Examined.	Per Cent. Failed.	Colleges, 50 to 100 Examined.	Total Examined.	Per Cent. Failed.	Colleges, less than 50 Examined.	Total Examined.	Per Cent. Failed.	Colleges, 100 or More Examined.	Total Examined.	Per Cent. Failed.
1904	149	6241	16.4	14	2271	11.7	28	1817	16.9	107	2153	31.0	794	43.1	43.1
1905	153	6411	18.3	14	2350	12.4	37	2543	17.7	102	1518	28.9	750	41.1	41.1
1906	146	6938	17.3	16	2504	14.5	34	2381	16.9	96	2043	21.3	1097	42.5	42.5
1907	146	6207	13.8	12	1826	12.7	36	2578	14.7	93	2003	13.6	1064	35.5	35.5
1908	137	6491	17.2	19	2596	15.6	26	1825	15.5	92	2070	20.8	1277	44.6	44.6

Besides the graduates of the medical colleges of the United States, 1,279 candidates were examined, made up of foreign college graduates, graduates of miscellaneous colleges and non-graduates, of which number 44.6 per cent. failed.

RESULTS IN HOME STATES AND ELSEWHERE

Table G is of much interest because it shows what portion of the candidates from each college took their examinations in the state where the college was located and what portion went elsewhere. Of the 5,948 recent graduates examined by state boards in 1908, 3,429 or 57.6 per cent. took their license exam-inations in the home state. Of this number 13.2 per cent. failed, while of those who went to other states 20.3 per cent. failed. The table allows a similar comparison of percentages to be made for each college as well as for each state group of colleges, the latter being shown in heavy faced type. A further description appears with the table.

TOTAL RESULTS FOR FIVE YEARS

Table H shows, so far as reports were obtainable, the num-ber registered and the number rejected in each state for each of the past five years. A comparison of this table with the statistics in the last educational number of THE JOURNAL (Aug. 15, 1908, p. 586), shows what would be expected, that the states having the largest number of medical graduates examine the largest number of physicians. In 1904 several states registered all or the majority of their applicants on the presentation of satisfactory credentials without written exam-inations. Now only one state, New Mexico, will register can-didates on presentation of a diploma, without examination.

This table shows only those registered by examination. Another table (M) shows the total registration by all methods.

CLASSIFICATION OF COLLEGES

Tables I, J, K and L give a classification of the medical colleges of the United States on the basis of the failure of their graduates at state board examinations during the past year. This classification is based on the examination of *recent graduates* as shown in Table C. In forming definite conclusions, the cautions hereinafter given should be observed, of noting the number examined, the number of states in which representatives appeared and the character of the boards making the examination. To form a more exact judgment one should compare the percentage of failures received by any college this year with those received in the classifications published in previous years.

Table I gives a list of 48 colleges which obtained failure percentages below 10 per cent., 20 of which had no failures whatsoever and 31 had less than 5 per cent. The failure percentage for the entire group was 3.6. Table J shows 29 colleges whose failure percentages were between 10 and 20 per cent., of which number 18 had percentages below that for the

group, which was 14.1. Table K includes 46 colleges having failure percentages of 20 per cent. and above, of which number 32 had above 30 per cent., 20 had above 40 per cent. and 10 had percentages of 50 per cent. or above. The highest percentages of failures were 77.8, 75.0 and 66.7, three schools receiving the last given. The percentage for all candidates from this group of colleges was 35.8. In Table L have been placed a number of colleges in regard to which data was insufficient to allow of fair comparison. This list contains 14 colleges, to which should be added the Epworth College of Medicine of Oklahoma, for which no examinations were reported.

COMPARISON WITH PREVIOUS YEARS

	Less than 10 Per cent.	10 to 20 Per cent.	Above 20 Per cent.	Unclassi- fied.	Total.
1904.....	47	27	38	37	149
1905.....	45	22	40	46	153
1906.....	62	24	43	20	149
1907.....	64	27	39	18	148
1908.....	48	20	46	15	138

A comparison of the classification this year with those of previous years shows a decrease in the number of colleges having less than 10 per cent. of failures and an increase in those having above 20 per cent.

This table is especially interesting, since it gives data relating to the 45 larger medical colleges arranged according to the number of graduates examined. This allows of comparisons between colleges having classes of nearly equal size.

Of the 19 colleges having 100 or more examined, only 8 have failure percentages of 8.5 or less, while 5 stand out prominently with large failure percentages of 30.3, 32.0, 34.5, 35.1 and 50.5. This marked difference holds even in respect to recent graduates (of 1903 to 1908, inclusive).

Of the 26 colleges having between 50 and 100 graduates examined, 12 had failure percentages less than 10; 6 had failure percentages between 10 and 20, and 8 had failure percentages above 20, the 3 highest having 33.9, 47.9 and 50 per cent.

The average percentages of failures for these larger colleges, for graduates of 1902 and previous years, was 26.9; for graduates of 1903 to 1908, inclusive (recent graduates), 14.5; for graduates of 1903, 11.6, and for graduates of all years, 15.5. Of the 45 colleges, 23 obtained failure percentages below the average. Of the 6,491 college graduates examined by state boards in 1908, these larger schools furnished 4.421, or 68.1 per cent.

of different states in which a school's graduates have been examined is important. The larger this number the more accurate will be the conclusions. Again, the character of the boards making the examination and the methods employed by them are important factors to be considered, since some boards

mark severely while others, which is especially true of partisan boards, may be very lenient. Finally in this connection it should be stated that the character of the license examination as usually conducted at the present time is such that graduates of colleges operated largely on quiz-class methods may be most successful in passing them. Therefore, the statistics herewith presented should be taken only as part of any investigation of medical schools, although it is an important part.

IN CONCLUSION

Our endeavor in the publication of these statistics has been to give an absolutely fair presentation of actual facts, knowledge of which is always beneficial. We feel sure this exposition of the results of the examination of applicants for license to practice medicine in the United States will help in the advancement of medical education in this country. Our acknowledgments are due to the state licensing boards whose ready cooperation and complete reports have made the publication of these data possible.

This table shows the total number registered during 1903 in each state by the various methods. The first column shows the recent graduates registered, the second column, the old practitioners (graduates of 1902 and previous years), the third column the non-graduates, and the fourth column shows the number licensed through reciprocity. To note that states which reciprocity have examined have registered very few "old" if exception is New York, which has arranged reciprocal relations with only five other states. The fifth column shows those registered without written examination under various exemption clauses. The last column shows the total number of physicians registered in each state during the year.

TABLE N.—PHYSICIANS REGISTERED THROUGH RECIPROCITY BY STATE EXAMINING BOARDS DURING 1908

Total received from each state through reciprocity...	1092	4	1	2	10	2	2	14	18	1	25	33	94	32	53	24	30	3	63	23	1	61	47	4	2	46	1	100	4	6	35	3	1	15	1	4	1	14	10	3	20	15	2	42

This table shows the number of physicians registered by each state through reciprocity during 1903. "Reciprocity" is not the best term to use, however, since some states, Colorado for instance, register candidates who have satisfactory credentials including licenses, regardless as to whether the state issuing the original license reciprocates with those states or not. Taking New York as an example, reading from left to right, the table shows that New York registered a total of 72 applicants through reciprocity during 1903, of which number 13 came from Michigan, 40 from New Jersey, 9 from Ohio and 10 from Vermont. Reading from above downward, the table shows that 100 physicians left New York during 1903 and registered in other states under the reciprocity provision, of which number 10 registered in Colorado, 1 in Connecticut, 1 in Louisiana, 5 in Michigan, 1 in Minnesota, 73 in New Jersey, 1 in North Carolina, 6 in Ohio and 2 in Vermont.

Colorado leads, having registered 150 physicians through reciprocity, followed by Kansas, which registered 104, New Jersey with 84, and Michigan with 83.

It is interesting to note in what states the original licenses were issued. The table shows that of 1092 applicants registered through reciprocity, 225, or over 20 per cent., obtained their original licenses in Illinois, 100 in New York, 94 in Iowa, and 63 in Michigan.

Altogether 1,092 licenses were issued through reciprocity in 1908, an increase of 103 over 1907, and 407 over 1905.

[illegible]

Medicolegal**Effect of Injury on Capacity to Bear Children Proper for Consideration**

The Second Appellate Division of the Supreme Court of New York holds, in the personal injury case of Devine vs. Brooklyn Heights Railroad Company, that evidence that the plaintiff's capacity to conceive would continue but that she would continually suffer the discomfort and pain of miscarriages, was competent on the question of damages, regardless of the question by which it came in, or of whether it cropped out. It is true, the court says, that the evidence could not be used as a basis for damages for pecuniary loss resulting from deprivation of future offspring, but it could be used as a basis for damages for pain and suffering, and was therefore material and relevant.

If the defendant's counsel feared that the jury might also make use of it to speculate as to how much pecuniary loss the plaintiff would suffer by having no more children to grow up and support and enrich her (after the manner in actions by next kin for deaths by negligence), it was for him to request the trial judge to charge the jury that such damages were not allowable.

It would not do to distort the charge of the trial judge on that head (to which there was no exception), namely, that the plaintiff was entitled to recover reasonable compensation for her pain and suffering, for the deprivation of her natural powers, for the loss of health which was due to this accident, if it was due to it. To say that she was entitled to damage "for the deprivation of her natural powers" was strictly correct, even if limited to a particular delicate meaning, which was not the case. That is true in the case of man or woman. But that is far from even intimating that damages may be given for pecuniary loss resulting from deprivation of future children.

Finally, it may be worth while to point out that the question itself was proper, namely, "What effect does it (the injury) have on her capacity to bear children?" It was just as proper as to ask what effect an injury has on the function, use or capacity of the arm, leg or stomach. The capacity may be made laborious, or painful, or destroyed. The degree of injury is competent to be shown. If the plaintiff were still able to conceive and bear children with regularity and certainty that would be evidence that her womb was not much injured or weakened, and that she could not do so would be evidence strong, corroborative evidence—that the physical condition testified to actually existed, namely, that the womb was retroverted and its ligaments greatly weakened.

Adulteration of Coffee with Lead Chromate

The United States District Court for the middle district of Tennessee, in the case of United States vs. 84 Sacks of Coffee, that coffee colored and coated with lead chromate, a poisonous and deleterious substance, whereby inferiority is concealed and the coffee rendered injurious to health, is adulterated within the meaning of the act of Congress generally known as the Food and Drugs Act of June 30, 1906, and that the coffee of that character seized should be destroyed by being burned.

3. Roentgen Rays in Thoracic Lesions.—Boggs says that out of a series of more than eighty patients whom he has exam-

ined for pulmonary tuberculosis, in whom the diagnosis has been confirmed either before or afterward by other methods, he feels justified in summarizing the following points:

1. The extent of the disease is more accurately determined by the x-ray than by the physical findings alone.
2. In doubtful cases the rays often afford sufficient information to make an accurate diagnosis.
3. The rays are a useful method of recording the lesions and of determining the progress made by treatment.
4. The radiogram records nothing but variations in density and leaves the etiologic factors to be determined by other clinical methods.
5. Frequently, when physical signs were present in one side, the radiogram would show infiltration in both lungs.

The Roentgen rays afford also a valuable method of diagnosing mediastinal tumors.

5. Point of View in Medicine.—Robinson cites instances to show the importance of keeping laboratory methods subservient to older and more reliable clinical methods. He insists on the importance of the art of medicine, which can not be based solely on the knowledge of the dead house or laboratory. In our efforts to get rid of tuberculosis, so praiseworthy and encouraging, we must not insist on foolish rules of prevention or cure, thus becoming absolutely cruel to those who most need our sympathy and support. He quotes the admirable counsels in this respect of the Massachusetts State Board of Health. He discusses alcoholism and prostitution, the relation of the general practitioner to the consultant, and the importance of trying to relieve symptoms of disease carefully and intelligently.

9. Aneurism of the Aorta and Tabes Dorsalis.—Bickel discusses the question whether the concurrence of these two affections in the same patient—which Lesser has shown to occur in approximately 20 per cent. of the cases of tabes dorsalis—is merely a coincidence, or whether we shall find in such cases tabes itself or a toxin peculiar to the two conditions to be the underlying cause of aneurism. There can be no doubt, he says, that syphilis is one of the most frequent causes of aneurism of the aorta as well as of tabes. He is inclined to believe that the association between the two diseases is merely accidental, and that in such cases each is a para-syphilitic disease independent of the other.

11. Cancer Treated with Trypsin.—Golley makes a further report on the two cases of cancer, formerly reported by him, in which the patients were treated with injections of trypsin. The first patient is in fairly good health and considers herself cured, although he suspects that she will have trouble in the future. At present she is free from pain, the surfaces are all healed and she is about her duties as though perfectly well. He describes the condition of the second patient from the fall of 1906 to the summer of 1908, when she died. Up to the last there was marked influence over the general physical condition whenever trypsin was used. The case was one of cancer of the large bowel. Three important points are, that it never became necessary to establish an artificial anus; that the disease changed from an active and rapidly progressive type to a slow and almost stationary one, not only prolonging life, but making it more bearable and wholesome by the formation of membrane over the raw surfaces; and that trypsin appears to exert some influence on the metabolic processes particularly, and to establish a resistance to the cell activity of malignancy.

- 15 Intermittent Hydronephrosis. Report of Four Cases (continued) D F. Jones, Boston
16 *Circulation of the Lobar Ganglia. J B Ayer, and H F. Aitken, Boston

13. Cancer of Tongue, Mouth and Jaw.—Greenough, Simmons and Green conclude their analysis as follows:

1 One hundred and seventy two cases of cancer of the tongue, mouth and jaw appear in the records of the Massachusetts General Hospital in the years 1890-1904 inclusive. Of this number 112 patients were operated on, 50 were judged inoperable, and 10 refused operation.

2 Of the 112 operations of all varieties, 20 resulted in death within 60 days (17.8 per cent.)

3 Of cancer of the tongue and floor of mouth, there were 98 cases, of which 62 patients were operated on and 36 cases were inoperable or the patients refused operation. Of the 62 patients operated on in 35 (56.5 per cent.) the end result is known; 62 cases of operation gave an operative mortality of 8, or 12.9 per cent. Of the 35 cases in which the end result is known, 10 patients were free from recurrence 3 years or more after operation (28.6 per cent.) Of the 40 cases in which recurrence did take place after operation, in 38 death occurred before the lapse of 3 years after operation. Operations for cancer of the tongue involving section or resection of the jaw caused a much higher operative mortality and no greater percentage of cures than the initial buccal operations.

4 Of cancer of the lower jaw, there were 40 cases. 28 operable, 12 inoperable. The operative mortality of 28 cases was 10, or 35.5 per cent. In 26 cases of operation the end result is known and in 5 cases (19.2 per cent.) the patients were free from recurrence 3 years or more after operation.

5 There were 14 cases of cancer of the upper jaw; 10 patients were operated on and 4 were not. The end result is known in 9 of the 11 patients operated on, and in each of these 9, death occurred within 3 years, although there were no deaths as an immediate result of operation.

6 Cancer of the tonsil, soft palate, or fauces occurred in 11 cases, 8 of which were inoperable and 4 were submitted to operation. One patient was alive and well 7 years after operation (25 per cent.) There was no operative mortality.

7 Cancer of the cheek occurred in 9 cases, 1 of which was inoperable. Of the 8 patients operated on, 2 died of operation (25 per cent.) and none was cured.

8 For reporting statistics of the end results of operations for cancer, a standard should be established, requiring the publication of reports of all consecutive cases entered in the hospital records. For the acceptance of percentages of cures pathologic proof of the existence of carcinoma should be presented, and no case should be considered in which the patient has not survived the arbitrary 3 year period.

16 Circulation of the Lobar Ganglia.—This is a supplement, consisting mainly of half tone illustrations. Ayer's and Aitken's findings endorse those of Heubner concerning the anatomy of the circulation of the lobar ganglia—a point of great importance in regard to cerebral hemorrhage—which are at variance with those of Duret at present generally accepted. The essential differences from Duret's teaching are, that the present findings show that the middle cerebral artery has not plainly the predominant share in the circulation of this region, that the caliber of the anterior cerebral artery is not insignificant, but is equal to that of the middle cerebral artery; and that the posterior cerebral artery is not more important than the anterior cerebral artery. Further, the lenticulo optic artery of Duret has not been found in either side of 45 brains (Heubner does not mention it after dissecting 30 brains). The choroid artery supplies the posterior third of the putamen slightly, the globus pallidus, and the inner part of the internal capsule.

32 *Diphtheria Involvement or Contamination of Wounds. E L Tuohy, Duluth.
33 Case of Foreign Body in the Trachea. D W Rudgets, Yankton, S. D.

32. Wound Diphtheria.—Tuohy reports two cases of wounds which have become infected with the diphtheria bacillus. One case was that of a finger, infected in the lumber woods, which had been opened and dressed, but refused to heal. When seen three months later, there was tremendous induration in the axilla, with three sinuses. Actinomycosis was suspected, but pure cultures of the diphtheria bacillus were found on examination. Antitoxin treatment resulted in cure. The second case was a suppurative bunion that had been opened and drained. This also became chronic. When seen one month later investigation here also showed pure cultures of the diphtheria bacillus. A cure was effected in this case too by antitoxin injection. It was found that diphtheria cases were being treated in the town and in the hospital from which these men came at the time they were first under treatment. Tuohy suggests that cases of similarly persistent wounds that defy healing without any obvious cause after incision and drainage and under appropriate treatment, should be examined for the diphtheria bacillus, and if this is found, a prompt cure can be promised almost with certainty.

34 Typhoid Diet.—Robertson summarizes the views of 13 prominent clinicians in reply to his inquiries practically as follows: The majority of his correspondents advocate liquids, milk and eggs as the chief dietary. One disapproves of milk on the ground of its causing tympany; but the majority of patients taking that diet with impunity as against the minority is obvious. The precautionary measure cited is to discontinue the milk in case of curds, tympany, etc, but until these symptoms arise, so long as the patient is doing well and is nourished, it is useless to ignore such a valuable food stuff. Robertson supposes it could be shown that almost any other of the generally advocated foods listed could cause, seemingly, a disagreement with the digestion. Broths might act as a culture medium, eggs are regarded as suspicious sometimes, and we are advised to cut off nearly everything in tympany, etc. Even water is possibly taken to excess at times. He knows of but two guiding lines in typhoid fever diet, and they are, to nourish the patient and to have respect for the local conditions in the digestive tract. Finally, he believes that he would be safe in advancing this proposition: Give the patient a sensible nurse and an obtusely bent glass feeding tube, and tell the nurse to give the patient anything that may be easily taken through it, and if curds (when milk is the staple diet) occur, to cut off milk, using in its stead whey with essence of pepsin; or, to give even water only for a few days, should tympany, etc., arise. His correspondents show all these points.

67 Meningococcus Septicemia, with Sterile Cerebrospinal Fluid; Iridocyclitis; Flexner's Serum; Recovery. D. Bovard, Jr., New York.

58. Sarcosporidiosis.—Darling reports a case of sarcosporidiosis occurring in a negro who passed through an attack of typhoid accompanied with necrosis and myositis of some muscles. Sarcosporidiosis in man is probably extremely rare and doubtless represents a chance infection, by one of the sarcosporidia. Its customary habitat is one of the domestic animals, and it differentiates the sporozoon from that of St. Remy. These infections appear to cause no discomfort and the clinical condition is mainly attributed to the typhoid.

Value of Chest Expansion.—Goodall and Belknap draw the following conclusions:

The measure of chest expansion has no constant direct relation to lung capacity, and by itself is of comparatively little value as one of the methods of physical examination. Large measures indicate good development of the muscles which expand the chest. On the other hand, small variations, normal standards can not be adopted. However, that an expansion of from 2 to 3 inches at the maximum capacity under ordinary conditions is a fair standard.

The measure of lung capacity varies directly with muscular development, provided the individual measurements may be drawn from a group of normal lungs. Unless special attention is given to the method of measurement, values of 190 cubic inches, and possibly less, are normal for adult males. Measurements large values only indicate good muscular development. Low values indicate inferior muscular development and improper breathing.

In suspected pulmonary disease, very little, if any, additional aid is obtained by these measurements. The only positive use of the measurements is the aid in determining whether or not the person is breathing properly, and whether or not the muscular development is properly developed.

Tuberculous Lesions in Infants.—Wollstein summarizes his paper practically as follows:

Of 185 cases showing tuberculosis at autopsy there were 13 in which the tuberculous lesions were limited to the respiratory tract, and only 1 involving the intestines alone. The point of entrance for the tubercle bacillus in these 14 cases was clearly in the lungs 13 times and in the intestinal tract once.

In the majority of cases of extensive, generalized tuberculosis in young children the exact point of entrance must remain in doubt. Although the lungs were involved more frequently than any other organ (in 96 per cent. of all cases), this proves their marked predisposition to tuberculosis rather than their primary infection.

This study shows how comparatively rare undoubted cases of intestinal tuberculosis were in this series of infants and children under 3 years of age; and how, even when due allowance has been made for all doubtful cases, tuberculosis of respiratory origin predominated over that due to ingestion of the bacillus in these subjects.

62. Primary Portal Thrombosis.—Lewis and Rosenow report a case, summarize the twenty cases from the literature, discuss the symptoms, diagnosis and treatment and draw the following conclusions:

1. A careful bacteriologic examination of the blood, using media which favor the growth of the highly parasitic bacteria, will establish the etiologic rôle that bacteria play in portal thrombosis.
2. It is impossible to differentiate between thrombosis of the mesenteric arteries and veins, but a probable diagnosis of circulatory ileus can be made if the history reveals some previous illness that is frequently associated with inflammatory changes in the arteries and veins.

3. The procedure to be adopted depends altogether on the conditions revealed by the exploratory operation. A record of four recoveries in twenty-one cases in which operation was performed, indicates that surgical intervention is not futile.

71 *The Ice-Bag in the Treatment of Typhoid Fever. G. T. Smith, U. S. Navy.
72 *Treatment of Typhoid Fever by Colon Irrigations. C. G. Alderman, U. S. Navy.

71. The Ice-Bag in Typhoid.—Smith speaks highly of a large abdominal ice-bag covering the whole area below the umbilicus and kept there constantly until the temperature falls to normal. A towel is used beneath the bag. The effect was markedly beneficial, no baths or spongings were required, no tympanites occurred, and there was no delirium or hemorrhage from the bowels.

72. Colon Irrigations in Typhoid.—Alderman reports the successful result in an epidemic of typhoid at the United States Naval Hospital, Las Animas, of a treatment previously unsuccessfully tried and discarded. If the patient is seen before the eighth day he is purged freely with calomel, 3 grains, sodium bicarbonate 5 grains, followed in three hours by half an ounce of magnesium sulphate. If seen after the eighth day the physician must exercise his judgment as to whether purging is safe. A low enema is given when a bowel movement is pending, and, immediately following, a high enema at 85 F. to flush the colon—between 1 and 2 quarts. Both enemas are of plain water. The next two enemas are to be given at a temperature of 80 F. and dropping to 70 F., at which temperature they will be continued. They are given at three-hour intervals so long as the temperature is above 100.6 F. Milk from 5 to 6 ounces is given every three hours with lime water; also all the water the patient wants to drink. Neither diarrhea nor constipation is a contraindication. He discusses the rationale of the process, and says that it is not plain that this treatment reduces the temperature after each enema, as baths do, but the fastigium is lower; and if any symptoms of septic absorption are present they are scarcely noticeable. No delirium is seen, nor is there the anxious look, the dull heavy eye, the muscular twitching, etc. The patient complains of no headache or other pain, has a bright appearance, and there is little or no tympany. The patient actually loses the so-called typhoid facies which every physician is accustomed to see.

- 73 *Streptothricosis, with Special Reference to the Etiology and Classification of Mycetoma. W. E. Musgrave, M. T. Clegg, and M. Polk, Manila.
74 Trichocephaliasis. W. E. Musgrave, M. T. Clegg, and M. Polk, Manila.

73. Streptothricosis.—Musgrave, Clegg and Polk remark on the confusion in nomenclature resulting from the transition from a clinical picture to an etiologic diagnosis, and to the discovery that to the same organism that produces Madura foot, lesions in the other parts of the body are found also to be due. They discuss the different methods of classification adopted by botanists, describe animal experiments, and review the literature of the subject with the following resulting conclusions:

There is in human pathology, a very important group of branching, filamentous micro-organisms which logically belong to a single genus. The generic name is variously given as *Streptothrix*, *Actinomyces*, or *Nocardia*; the last of these names is probably scientifically the most correct, but because of the present botanical confusion and uncertainty the first is here employed, because of more general acceptance.

The following species, to judge from our work and from a study of the literature, are the most important and may be recognized as established. There are probably a number of others but the descriptions of many of them are too imperfect to allow of their recognition: *Streptothrix actinomyces*, Boström, 1890; *Streptothrix wolfei*, Wolf and Israel, 1891, and Wright, 1905; *Streptothrix nocardii*, *Streptothrix madurae*, Vincent; *Streptothrix silberschmidti*.

The disease caused by infection with these parasites is properly named streptothricosis, with actinomycosis and nocardiosis as synonyms. Other names, such as lumpy jaw, Madura foot and mycetoma, should be considered more as describing anatomic localities.

rather than as designations relating to any special or specific cause of infection. Mycetoma might well be taken as the correct name for the group of infections if a strict interpretation of rules of nomenclature is followed, but usage renders it perhaps more desirable to retain the name as representing *Streptothricosis pelvis*. If mycetoma is to be considered in any more comprehensive light than this, it should become another synonym for streptothricosis. It should not be considered a disease caused by organisms other than *Streptothrix*.

They then discuss streptothricosis (synonyms: actinomycosis, nocardiosis), which they define as an infectious disease of man and animals caused by one or more species of *Streptothrix*. They tabulate their experiments. As to treatment, potassium iodid in large doses over a long period is generally admitted to have a favorable influence on the course of the disease, and complete cures have been reported; locally, antiseptic dressings and the Roentgen ray, surgical measures, drainage, removal or amputation were employed, according to the locality and extent of the lesion. A combination of all these forms would seem to promise the most favorable opportunity for recovery.

75, 76. Abstracted in Department of Medical Economics, THE JOURNAL, May 15, 1909.

78. Published also in *Southern Medical Journal*, February, 1909. This paper appears to be in the main identical with that read before the Western Surgical and Gynecological Association and abstracted in THE JOURNAL, Jan. 30, 1909, p. 413.

79. Thermic Crises in Locomotor Ataxia.—Campbell gives the history of a case supposed originally to be one of malaria, in which hard chill, followed by high fever, and later by sweating occurred at intervals; the highest temperature point recorded was 106.6 F. A striking feature was the lack of constitutional symptoms one would expect as an accompaniment of so high a body temperature. While Campbell can not assert positively that the high temperature attacks observed in his patient were tabetic crises, the facts that lead him to present them as probably of such a nature are:

1. Absence of any evidence of the usual causes that produce fever, either at the time of the attacks or after the attacks subsided, it appears very improbable that any of the usual causes apt to produce fever could produce such high temperature several times and yet leave the temperature as the only evidence of their presence.

2. The sharply paroxysmal nature of the temperature disturbance.

3. The fact that such occurrences, while very unusual, have been reported in the past.

80. The Free Tuberculous Dispensary.—Klein assigns the following as the functions of the tuberculous dispensary: To care for ambulatory cases, to refer incipient cases to sanatoria, to watch and supervise patients discharged from sanatoria, to examine other members of the family, to disseminate information, and to aid the health department. He discusses each of these points.

92. Sensations and Feelings Under Anesthetics.—Johnston gives a study of the sensations and feelings under ether in the case of two brothers, which lead him to the conclusion that the data in hand are insufficient to enable one unprovisionally to conclude anything definite concerning the fundamental psychologic problem as to what is the most serviceable conception of the relationship of sensation and feeling or affection. The special sense organs become inactive long before general consciousness is lost. Vision and audition cease before touch and sense of position. A feeling (anguish or anger, etc.) is the most persistent mental state. In the process of gradual recovery of normal consciousness feeling is first reinstated. Purely intellectual activity, without images, is next in order. Vague tactual sensations, pressure, and sense of position return before sight and hearing. All these, together with partial restoration of inhibitory power, are not sufficient to enable one, however, to feel normal, to be an inhibiting individual, or to grasp one's characteristic relation to one's environment. Physical pain seems to be here one of the necessary mental conditions for this self realization. Due chiefly to this intense mental activity, sleep is induced with great difficulty. Finally there seems to be some evidence, from this "feeling one's self as a disembodied spirit," from this conviction that all sensation is for the time localized in the head, and from the absolute loss of all inhibitory power and of the experience of pain, that there may be such a physiologic situation in which some so called higher centers work independently, paralleled by vivid, if not constructive, imageless, intellectual activities. In short, this field would seem to be a fruitful one for further and more comprehensive psychologic, as well as strictly neurologic, investigations. Such possible results might nicely supplement other at present more systematically directed methods into these as yet unexplained phenomena.

Legitimately, it seems, we may be inclined to justify the position of those psychologists, at present in the minority, who claim that there is no inseparable connection of sensation with feeling tone.

94. The Unconscious.—Prince concludes his analysis of the unconscious by a consideration of the evidence from dormant complexes which never form a part of the experiences of the personal self inasmuch as they originated in dissociated states, such as hypnosis, alternating personalities, dreams, trance and other hysterical conditions, etc. The origin and even the existence of such complexes is necessarily unknown to the personal self. In the psychologic results of suggestion given in hypnosis, known as posthypnotic phenomena, we have perfect examples, not only of the experimental formation of dormant complexes, but of the influences of these complexes on the personal consciousness, and we can study the mechanism of this influence, which has not hitherto received the attention it deserves. In it, too, we can study the psychologic principle of psychotherapeutics; for every therapeutic suggestion given in hypnosis, if successful, clearly becomes a posthypnotic phenomenon. Taking the facts of experimental investigation as data, Prince suggests three methods by which dormant hypnotic complexes affect the personal consciousness and, in fact, the whole personality: 1. Through the formation of co-conscious ideas. 2. Through the persistence of the emotions created in hypnosis. Although the ideas giving rise to them disappear, the prevailing feelings, whether joyous or depressing, aroused in hypnosis remain,

wherefore it is important to take care before a subject is allowed to wake, that depressing ideas are removed and those with a healthy, invigorating, emotional tone implanted. The power of emotion in invigorating or depressing all vital processes according to its character is well known. Moreover, the persistence of the emotional tone after the rest of the complex becomes dormant is not peculiar to posthypnotic phenomena, but is observed in every-day life. The difference between them is that in one case we can, if we will, and in the other we can not recall the origin of the feeling, but in either case we do not. Dormant dream complexes may give rise to similar phenomena. 3. Suggestion in hypnosis gives rise to fixed ideas, which persist after waking as organized unconscious complexes. Then, as a result of stimulation by associated ideas from the environment acting as *points de repère*, these complexes become conscious again and interwoven with, and substituted for, the ideas which happen to be in the personal consciousness at any given moment. He discusses this subject at some length.

98. Intestinal Autointoxication.—Anders says that the disease is often attributable, not so much to microbic action as to the products of intestinal fermentation. There are three main factors: (1) Ingestion of excessive albuminous food; (2) certain intestinal lesions, including defective motility; (3) abnormalities of metabolism. From personal observation, Anders is also convinced that fat and sugar, taken in quantities above the physiologic capacity of the organism, are responsible in certain cases. When the eliminative processes are defective a marked predisposition to the condition exists. Cases should be subdivided etiologically into gastric and intestinal forms of chronic autointoxication. The great majority of cases, however, are of intestinal origin. He discusses the symptomatology and says that his personal experience indicates an increase in the elimination of indican in practically all cases. He has further demonstrated the fact to his own satisfaction, that indican is increased most decidedly in the cases showing marked residual accumulation throughout the colon. This urinary constituent, therefore, is of the utmost importance for both diagnosis and prognosis, and chemical examination of the urine. The microscopic urinary findings are unimportant. He has observed marked acetoneuria in the preponderating proportion of his cases of intestinal origin. The nervous system, more particularly the vasomotor tract, is decidedly affected by the irritant auto-toxins. It is exceedingly important, however, to distinguish between nervous disturbances induced by the absorbed toxic substances and those resulting from primary changes in the neuromechanism of the body. The diagnosis of this condition should always be made with caution and reserve. It is not permissible to regard the given case as one of chronic alimentary intoxication, retrospectively, merely because the symptoms have disappeared as the result of an eliminative plan of treatment, since this method also serves other dis-

posing and exciting causes. In connection with the principal causative factors—notably impaired metabolism, dietary errors, and certain pathologic conditions of the intestinal tract, e. g., mucous colitis and chronic appendicitis—the following symptom group would suffice for an assured diagnosis: Heavily coated tongue, fetor of breath, indications of Rigg's disease, headache at intervals, insomnia, marked constipation, evidence of fecal accumulation in the colon, the elimination of an increased amount of indican and the frequent presence of acetoneuria. Though experimental evidence may be wanting to show that the development of gout, arteriosclerosis, nephritis, and other forms of degeneration is, in some instances at least, dependent on autointoxication, clinical experience and observation lend striking confirmation to this view.

99. Smallpox.—Armstrong states that the diagnosis of this disease must often rest wholly on the objective lesions of the skin.

1. Except in rare instances, and only in the presence of an epidemic, is the positive diagnosis of smallpox justified before the appearance of the skin lesions.

2. The history of pre-eruptive illness serves only to confirm the diagnosis as made by the senses of sight and touch.

3. The smallpox papule has characteristics which make a positive diagnosis possible within a few hours of its appearance.

4. The papules appear first on the exposed parts, particularly the forehead and flexor surfaces of the wrists. They are under the epidermis, hard, round, flat-topped, umbilicated, rose-pink, and waxy in appearance. All these characteristics are usually present.

5. In general, the entire course of evolution of the lesion from papule, vesicle, pustule, to scab formation is regular and characteristic.

6. The lesions vary in number. They may be few, or so numerous as to become confluent, but the individual characters of the lesion are present in all cases.

100. Fibroid Degeneration of the Appendix.—Morris gives the following as the salient diagnostic point in cases of fibroid degeneration of the appendix in the following order of importance:

1. Hypersensitiveness at the site of the right group of lumbar ganglia.

2. Distention of the cecum and ascending colon as far as the hepatic flexure, and this distended part of the bowel is filled with gas.

3. More or less persistent discomfort at the site of the appendix.

4. The presence of an intractable intestinal dyspepsia for which no other cause has been found.

5. Lastly, palpation of the appendix in many cases will bring out clear evidence of a small, hard, fibrous appendix.

103. Medieval Laboratory Diagnosis.—Walsh cites some interesting passages from the works of Cardinal Nicholas of Cusa, who lived in the middle of the fifteenth century, to show that he recommended the estimation of the pulse, and of the respirations by the clepsydra, or water clock, and also the application of the method of specific gravity to the urine and possibly the blood.

104. The Red Ring in Heller's Test.—Dawbarn calls attention to a diagnostic sign sometimes found in the urine. On contact with cold nitric acid, with or without the presence of the white line of coagulated albumin, there is to be seen, and far from rarely, a red line of varying width. It is never so sharply defined at its points of contact with the acid below, and the urine above, as is the line of albumin, but it is to be recognized with the utmost ease. When albumin is also present the red line in question will be found just above the albumin.

108. Acute Ascending Paralysis Following Antirabic Treatment.—Fabricius reports a fatal case of acute ascending paralysis following antirabic injections subsequent to the bite of a dog. Examination showed the dog not to have had rabies, and it is concluded that there was a causative relationship between the antirabic treatment and the disease.

120 Published in the *Lancet*, Dec. 12, 1908.

121. Anterior Metatarsalgia.—Forbes discusses the literature and the history of this subject. Its causation he divides into general and specific. The general causes are general debility and excessive body weight in proportion to the strength of the foot. The specific causes are: 1. The use of too short or too narrow a boot causing extension of the proximal phalanges with flexion of the distal phalanges. This results in a depression of the arch as is clearly demonstrated in casts of feet in this condition. 2. The use of a boot with too high a heel throwing the body weight on the anterior arch. 3. The use of a boot with too thin a sole, which insufficiently protects the anterior arch. The symptoms are as follows:

- 1 Pain—either of a constant character or spasmodic, as described by Morton
- 2 Tenderness—found on pressure from beneath over the heads of one or more metatarsal bones, or on lateral pressure in the region of the metatarsal phalangeal joint
- 3 Swelling and edema—may be so severe as to simulate gigantism, erythromelalgia or acromegaly
- 4 Extension of phalanges—often postural and accompanied by flexion of middle and distal phalanges. This may simulate deformities following anterior poliomyelitis
- 5 Muscular spasm—usually of extensors of toes. It is reflex in nature and causes a deformity resembling the conditions in No. 4.
- 6 Callosities on sole—frequent, and adding to the pain of a mild case

The diagnosis of anterior metatarsalgia requires its differentiation from: (1) The chronically strained posterior arch; (2) tuberculosis of the tarsus, rheumatism, the so called rheumatoid disease, and gout; (3) gigantism, erythromelalgia or acromegaly; (4) postural deformities, and (5) deformities resulting from the paralyzes. The treatment naturally resolves itself into (1) protection against lateral pressure, and (2) the elevation or support of a depressed arch, with suitable protection of the plantar surfaces of the heads of the bones. The elevation of the forepart of the foot is also of importance. Operative treatment, as suggested by Morton, should be applied only in those chronic or resistant cases in which conservative treatment has failed. In certain cases characterized by great spasm of the extensors, causing extension of the toes, the transference of the attachment of these tendons to the dorsal aspect of the heads of the metatarsals may be considered

132 *Retinal Hemorrhages and Arterial Hypertension. E M. Blake, New Haven.

132. Retinal Hemorrhages.—Blake says that the frequent association of retinal hemorrhages with disorders of the circulatory system emphasizes the close relationship between ophthalmology and internal medicine. The significance of a retinal hemorrhage extends beyond the disturbance of vision produced to some profound disturbance of the bodily function. The earliest definite signs which allow one to diagnose sclerosis are three: First, the corkscrew appearance of the small twigs at the macula and periphery; second, flattening of the veins by the arteries; and third, the dull red congestion of the nerve head. This last sign is thought by Reber to indicate a more advanced stage of the process. Retinal hemorrhage may be grouped into four types: (1) simple hemorrhage into the fiber layer of the retina; (2) hemorrhagic retinitis, that is, hemorrhage with some edema and exudates in the retina; (3) subhyaloid, a hemorrhage between the retina and the hyaloid membrane covering the vitreous; and (4) vitreous hemorrhage, an extravasation sufficient to burst into the vitreous humor. If a patient in middle life comes complaining of a blur of sudden onset, he should not be told that it is a trifling affair which will pass off, but a careful fundus examination should be made, best with a dilated pupil. If a little extravasation of blood or any evidence of vascular changes be found, which often can be detected in no other way in the early stage, the case should be thoroughly studied by the internist. The examination of the urine, blood, and especially blood pressure, which is so easily determined, may point to the necessity for medication and changes in the life habits which may spare the patient serious accidents and give him many years of life.

137. Treatment of Leukemia.—Baldauf suggests the injection of bacterial toxins in the treatment of leukemia. He bases his suggestion on certain observations of Dock and Longcope. The author's results in myelogenous leukemia, although not entirely satisfactory, give him reason to hope for much more from selected and more favorable cases with the use of Coley's fluid.

138 Laboratory Diagnosis.—Harris says that while the value of a laboratory report depends on the skill, experience, and intelligence of the laboratory worker, no amount of skill on his part will compensate for carelessness or ignorance on the part of the physician who secures the material. The laboratory report should be valued as only one link in a chain of evidence. A simple negative report is valueless unless it coincides with all the clinical manifestations. The microscopist should never be permitted to make the diagnosis; neither should he be expected to relieve the physician of the necessity of a thorough clinical study of the case.

139. Interrelations Between Medical and Legal Professions.—Fry points out the essentially different viewpoints in law and medicine, when it comes to the question of adjusting the rights and privileges of individuals and of society. He in-

10. Treatment of Heart Disease.—Barr says that there are very few chronic diseases so amenable to treatment and so compatible with a long life of comfort, if judiciously handled, as those of the heart. Rheumatism holds the first place in its causation. In rheumatic fever there is a marked increase of sarcolactic acid, therefore all foods, such as starch and milk, which give rise to formation of lactic acid, should be omitted. There is also a tendency to fibrin formation, so that everything containing lime, *e. g.*, milk, and its preparations, cheese, gelatin, and animal jellies, should be interdicted. Also, lime raises the blood pressure. An excellent diet for rheumatic fever consists of plenty of hot water, mincemeat and poached eggs, pounded chicken, steamed sole, and other nitrogenous foods. If a carbohydrate is required, well-boiled porridge may be given. Oranges and lemons may be freely used, and later, a fair amount of farinaceous food with plenty of fruit and vegetables, but no milk. Patients with mitral lesions should drink as little fluid as possible, not more than two pints a day, and should be kept on a light dry diet. Alcoholic drinks should be interdicted, tea and coffee with cream may be taken. Lemon squash is a good drink. Tobacco should be forbidden, and in any tendency to edema salt should be eliminated from the diet. Barr then discusses the hygiene, particularly recommending the morning bath from 60 to 90° F., followed by coarse friction. He goes at length into the questions of rest, exercise, and medicinal treatment, under which last head he particularly warns against excessive lime salts in the blood. There is no condition of the heart in which alcohol is beneficial, save spasmodic affections, and in these nitroglycerin, morphin and atropin are better remedies. Patients with heart disease do better without tobacco. By the method of treatment he details—which should be read in its entirety—Barr asserts that not only may the progress of degenerative heart lesions be stayed, but often their onset may be prevented.

15. The Intake of Fluids.—Haig holds that the amount of fluid usually taken is more a habit than a necessity. Most patients can reduce their fluid intake with benefit to 30 ounces a day, and with the help of fruit to 25 or 20 ounces. Salts, salines, and diuretics call for more fluids. By diminishing the fluids the blood pressure can be lowered 20 or 30 mm. of mercury, thus enabling some high pressure cases to turn the balance. The gain to a diseased or dilated heart is obvious. The objections to be considered are the retention of urates and constipation; but in cases of heart disease these are secondary considerations and may be dealt with by other means, *e. g.*, a purin-free diet for the urates, and laxatives for the constipation.

16. Tubercle Bacilli in the Blood.—Forsyth says that tubercle bacilli may commonly be found in the blood of tuberculous patients. Using Rosenberger's method (*American Journal Medical Sciences*, February, 1909), he examined the blood in 12 cases of pulmonary tuberculosis, in 10 of which there were distinct physical signs, with tubercle bacilli in the sputum. All showed tubercle bacilli free in the blood. They were few in number, not grouped, and found with difficulty. In one case phagocytosis was noticed, in only one was there evidence of mixed infection in the blood. Forsyth points out that if it be completely proved that living tubercle bacilli

occur in the blood of practically every tuberculous patient, no matter how early or circumscribed the lesion appears to be, without doubt our ideas as to the use of tuberculin must be considerably modified. The method of examination is as follows: The skin of the front of the forearm is thoroughly cleansed with liquid soap, alcohol and ether. A tourniquet is applied, and with a sterile syringe fitted with a platinum-iridium needle, previously flamed, about 5 c.cm. of blood are drawn from any convenient vein. The blood is at once mixed with about an equal volume of sterile citrated salt solution. The mixture is placed in a swift running centrifuge for twenty minutes, and some of the deposit taken up on a slide to form a thick film. This is dried in an oven at 60° C., and is then placed in sterile distilled water to lake the blood. Thereafter the film is fixed and stained in the usual way.

- 21 Renal Calculus. A. Fullerton.
- 22 *Treatment of Labor in Contracted Pelvis. F. Schauta.
- 23 Primary Carcinoma of the Vagina. G. W. Fitzgerald.
- 24 Oxalate of Cerium. J. C. McWalter.

22. Contracted Pelvis.—Schauta describes the development of the principles governing the treatment of labor in cases of contracted pelvis. He divides the operation into three main groups: indicated measures, prophylactic operations and surgical operations. The first includes those operations indicated, not so much by the pelvic contraction, as by complicating anomalies of labor. They are the application of the forceps with the head in the pelvis, turning from a transverse presentation, breech extraction, craniotomy on the dead child, and decapitation. The prophylactic operations are interruption of pregnancy and prophylactic version. Some place the application of forceps above the brim in this group. The surgical operations sacrifice the integrity of the mother's tissues in favor of the child by widening the pelvic space—symphyseotomy or hebotomy; or by providing an artificial channel—Cesarean section. He discusses how far, in cases of contracted pelvis, we can count on spontaneous birth. It affords by far the best solution of many complicated problems and is more frequently possible than appears from statistics. By premature interference many cases of labor are directed into a wrong course and result in great injury to mother and child. At Schauta's clinic about 80 per cent. of the births with narrow pelvis actually occur spontaneously, taking into account only full-term births. The expectant treatment gives by far the best results for the mother, as regards both mortality and morbidity. He does not find that the prophesied evil consequences occur. With regard to Cesarean section, he holds that while we must not perform any operation without the consent of the patient, assuming this general consent, the choice of the operation should be left in all its details to the operator. It is high time that we should break with the tradition of the time when Cesarean section was a deadly operation. It is the habit of making an emergency operation of it that is the cause of such troubles and dangers as occur—insufficient preparation of patient, instruments and physician's hands, and a patient already exhausted and possibly septic. The idea that the country practitioner should not perform Cesarean section will disappear when he is trained to that as he is trained to the use of the forceps, etc. Reviewing his experience he says the management of labor in contracted pelvis will shape itself in the future in the following simple manner, provided it is carried out from the very commencement in a skilful manner and in an institution under strict asepsis. In patients with a conjugate above 8 cm. there is a possibility of spontaneous birth, and therefore expectant treatment is to be adopted. In women under 8 cm., Cesarean section is to be kept in view. In cases bordering on the above, *i. e.*, a conjugate of from 8.5 cm. to 7.5 cm. hebotomy is to be considered. This operation in a conjugate of from 8 cm. to 8.5 cm. would be an alternative operation to spontaneous birth; in a conjugate of 7.5 cm. to 8.5 cm. an alternative to Cesarean section. The choice would be determined by the size and hardness of head, the strength of labor pains, the voluntary efforts and general condition of the patient.

This method of treatment should be looked on in the future as typical. All other methods hitherto used in the treatment of labor in contracted pelvis should be looked on as non-typical.

39 *Chronic Infantile Paralysis Diagnosed as Morbus Coxæ. F. Hernaman-Johnson.
40 Operative Technic of a General Practitioner. A. J. F. Clarke.

32. Death Rate of Diabetes.—Williamson says that the death rate from diabetes mellitus in England and Wales is steadily increasing. He discusses the etiology in reference to age, heredity, race, occupation and social position, sexual relations, diet, the use of alcohol and sweet beverages, psychic conditions, physical overwork and overstrain, pregnancy and external injuries, and also its association with other diseases, obesity, gout, acromegaly, and occasionally the climacteric. "But," he says, "whatever may be the pathogenesis of diabetes, the previous history of clinical patients shows that certain antecedents of the disease are common, i. e.: (1) Mental anxiety, shock, overstrain; (2) excess of alcoholic beverages; (3) excess of sweet foods, or beverages containing sugar." Also, in many cases—at least 22 per cent.—there is a family history of the disease. Preventive treatment should be instituted when the onset of diabetes may be considered likely from family history, in Jews suffering from overstrain, obesity, excessive food and little exercise, in women with grape sugar in the urine during pregnancy, in all cases of gout, acromegaly and obesity, in men of 40 or 50 who have suffered prolonged mental strain, in very stout women after the climacteric, after an acute illness or examination for life-insurance when temporary glycosuria has been found, and in all cases of slight permanent glycosuria. In all cases the following precautions should be taken: All articles of diet or drinks containing sugar should be avoided. A moderate amount of starchy food is permitted unless glycosuria has been detected. Sugar is more powerful than starch in producing glycosuria. Excess of food should be avoided. Sufficient out-door exercise is necessary. Dyspepsia and constipation should be treated. If possible an occupation should be chosen that reduces mental worry, anxiety, etc., to a minimum.

39. Chronic Infantile Paralysis.—Hernaman-Johnson records two cases of chronic infantile palsy, both treated and diagnosed as tuberculous disease of the hip. Both these conditions are amenable to treatment, but of a diametrically opposite nature, in the one case, stimulation and exercise being called for, in the other physiologic rest. The importance of diagnosis is therefore insisted on, and after a discussion of the case the author sums up the diagnosis as follows: In cases of general weakness of a lower limb in children, with symptoms referred chiefly to the hip, do not be over-ready to diagnose morbus coxæ. If possible, conduct the physical examination before hearing anything of the history, either personal or family. If aware of the existence of tuberculous diathesis, be on your guard.

1. Pain.—Examine for this by (a) striking the heel in a direction perpendicular to the leg, the patient lying down and holding the limb out stiffly; (b) jamming together the trochanters with both hands; (c) likewise the iliac crests. Next, manipulate the ankle, knee, and hip joints in all directions, at the same time noting any limitation of movement. Apply Thomas' test to detect permanent flexion of the thigh. Do not ask the child if these things hurt, but watch for wincing or expression of pain in the face. If all these tests are negative, the presumption against the existence of morbus coxæ is very strong indeed.

2. Paralysis.—Find out how far voluntary movement can be carried out. Especially look for weakness of the extensors of the foot. A tendency to foot-drop without contractures is almost diagnostic of infantile palsy. If retraction of the calf muscles exists, the evidence is of less value. The application of the faradic current to the muscles is of use in investigating a case; a feeble or absent response indicates nerve lesion.

3. Tumor.—Remember that when the glutei are markedly flattened, the trochanter may stick out, giving the appearance of a tumor. Careful comparison with the sound side will reveal the fact that the enlargement is apparent only. In case of doubt, a radiograph should be obtained.

4. Symptoms.—Not till the physical examination has been completed, should symptoms be inquired into. Pain is generally complained of, but always as the result of exertion. In some cases of infantile palsy, a walk of 100 yards may cause aching of the limb for hours, often spoiling a night's sleep. The pain, however, is not acute, being always described as an "aching" or "dragging" character; it is not brought on by an accidental knock or jar; and never takes the form of "night starts." The general condition in cases of infantile paralysis is often as bad as, or worse than, in tuberculous hip: poor nutrition, bad appetite, and digestive troubles being the rule.

5. History.—Parents nearly always attribute these afflictions of the lower limbs to a fall in infancy of early childhood. Such statements are generally to be regarded as valueless, except in so far as they help to fix the date when the disease was first noticed. A history of extreme chronicity, from five to ten years without much alteration in the condition, is strongly against the existence of tuberculous disease.

- 58 *Postoperative Embolism in the Lung. C. Lenormant.
59 *Perineal Prostatectomy by the Ischio-bulbar Route. Soubeyran.

58. Postoperative Embolism in the Lung.—Lenormant has observed four cases of lung complications after laparotomies or removal of the breast, a proportion of 0.5 per cent. of 792 operations during the last four years. He ascribes the thrombosis to infection, not necessarily occurring during the operation but possibly traceable to the paralysis of some part of the digestive tract with absorption of septic matter. He reviews the literature on the subject, and states that in 233 cases on record the embolism proved fatal in 106. The only treatment is by prevention, and he advocates digitalis or other suitable drug when, before the operation, the pulse is small and the heart action weak and irregular, and also in case of large abdominal tumors. In the same way injections of salt solution are indispensable, he believes, before attempting any operation when the patient is anemic from profuse hemorrhage or the arterial tension is much reduced, and the anesthesia should be as brief as possible. Ranzi advises preliminary scopolamin-morphin to reduce the amount of chloroform; Witzel prefers ether, as it is less depressing for the heart. In operating, the veins must be managed care-

one or two weeks in the majority of his cases. When the pains were severe during the first two or three days, as in a few cases, he inserted a suppository of morphin or codein with belladonna, but a dressing of aluminum acetate was generally sufficient and even this was not necessary in some cases. In others slight cauterization with silver nitrate or dusting with calomel or bismuth may have hastened the healing of the ulcerations.

74. Summarized in THE JOURNAL, July 4, 1908, p. 73.

76. **Diagnosis of Gastric Cancer from Cytologic Examination of the Rinsing Water.**—Marini gives an illustrated description of the characteristics of the tumor cells found in the rinsing water in 37 cases of gastric cancer, comparing them with the epithelial cells found in the stomach content in health. He urges that search for tumor cells in the water after lavage of the stomach is the easiest, simplest and most reliable diagnostic measure at our command and may reveal the existence of carcinoma even in its incipency. His illustrations show that the structure of the cells may indicate even the shape of the carcinoma, its location and other features. He is convinced of the diagnostic importance of even isolated tumor cells in the rinsing water, and relates the details of several cases in which the course of the affection later confirmed the diagnosis based on this finding.

78. **Suture of the Lung.**—Borchardt has recently operated in two cases of injury of the lung, and this experience in addition to study of the literature has convinced him that it is not necessary to attempt to suture the lung except when there is primary excessive acute or subacute hemorrhage, extensive pneumothorax or cellular emphysema or when the walls are much infected with a wide gaping wound. Except in these rare conditions it is wiser not to expose the patients to the dangers of an unnecessary operation.

81. **Relations Between Hypophysis and Ovaries.**—Thumim has made a special study of the relations between the ductless glands, and recently reported a case in which a tumor in the suprarenals was accompanied by atrophy of the ovaries and male characteristics in respect to growth of hair, bass voice, etc. In a case here described in detail, the loss of ovarian functioning coincided with the development of a tumor of the hypophysis and development of acromegaly. The patient had passed through a normal puberty, had married at 21 and soon after this the menses became irregular and finally ceased altogether, probably as the tumor in the hypophysis began to develop. The first sign of trouble was hoarseness; in a few months vision grew defective and Roentgen examination confirmed the assumption of a tumor in the hypophysis. The symptoms continued a progressive course under hypophysis tablets, but after a few months they seemed to be arrested

and the patient has remained in comparatively fair condition during the few months since, and refuses to allow any operation. It seems evident, Thumim thinks, that ovarian, rather than hypophysis treatment is indicated in this and similar cases, and the assumption seems plausible that disturbances resulting from excessive ovarian functioning, such as excessive menstrual hemorrhage, nymphomania and other psychoses, might be combated by hypophysis tablets. The pineal gland must also be considered in connection with the relation between the glands with an internal secretion. Not merely for organotherapy, but also for physiology and pathology these interrelations will surely prove a fruitful field for research.

83. **Streptococci in Children's Diseases.**—Ritter found streptococci on the tonsils almost constantly in 300 cases of tonsillitis, but only in 33 out of 117 cases of acute articular rheumatism. Streptococci were also present in the majority of cases of pemphigus and impetigo and in 23 of 100 cases of aphthous ulcerative stomatitis. In diphtheria in particular the presence of streptococci is the criterion of the imminence of the danger. In 100 cases of scarlet fever streptococci were found in only a few and none in the rapidly fatal ones. In all these affections, however, the streptococcal invasion was always secondary; in erysipelas alone the streptococci seem to be the causal primary germs, and they also seem to be the first on the spot in recent suppurations and acute infections of wounds, although they may be accompanied by staphylococci. The streptococci in all these affections are practically identical and their varying virulence depends on the soil. Examination of 16 patients with frequently recurring erysipelas, showing a peculiar affinity for this streptococcal affection, disclosed an abnormally small proportion of white corpuscles—below 4,000 and 5,000. This suggests that the blood of these patients is incapable of interposing an effectual resistance to the invasion of the streptococci. Antistreptococcus serum was injected in 22 severe cases of erysipelas, with good results. The tabulated findings show that in every case without exception the process was promptly arrested and subsided, in marked contrast to 87 other cases in which the serotherapy was not applied. In 19 cases of scarlet fever with streptococcus invasion 10 of the patients recovered under serotherapy. In 14 cases of diphtheria of the severest type the diphtheria antitoxin was supplemented by antistreptococcus serum and 6 of the patients recovered, all of whom he is confident would have been doomed without the serum.

84. **Pyelocystitis in Children.**—Göppert remarks that from 1.1 to 1.2 per cent. of the children brought to his office are suffering from pyelocystitis; he has notes of 130 such cases and here describes a few clinical types. The outcome depends on early appropriate treatment; fully 20 per cent. of his little patients succumbed, as medical aid was not sought until the affection was far advanced. Without treatment, all the severer cases in children under eighteen months inevitably terminate fatally, either during the acute attack or from chronic debility. A complete cure under suitable treatment may be anticipated, even when there are evidences that restitution is not complete for a year or two. Chronic trouble may persist and explain certain cases of menstruation pyelitis and pregnancy pyelitis in later years. Even in the most favorable cases a recurrence in the first two months may be expected in about 20 per cent. Subjective improvement may be counted on in two or three days under appropriate treatment and complete recovery in from ten to thirty days in infants, and more rapidly still in older children. The aim in treatment is to rinse out the kidneys by copious intake of fluids; infants require this even more than adults as they suffer so readily from lack of water. In case the symptoms are severe he advises pouring into the stomach, through a catheter introduced through the nose, from 150 to 200 gm. Carlsbad Muhlbrunnen water at a temperature of 40 or 41 C. (104 F.). In less serious cases he injects into the rectum two or three times a day a pint of warm Carlsbad water or lime water diluted to one-half. The transformation of the acid into an alkaline reaction in the urine hastens recovery, unless there is ammoniacal decomposition, in which case the

urine should be rendered acid. He found cranberry juice most effectual for this. His experience has further confirmed the benefit from salol or other drugs to attenuate the virulence of the bacteria. During the acute phase he gives from 0.05 to 0.2 gm. salol five or eight times a day to children from two months to three years old. Improvement is generally manifest in thirty-eight hours, but a copious supply of water must be kept up or further trouble is inevitable.

85. Irrigation Endoscopy and Galvano-Cauterization of the Urethra.—Goldschmidt's method of direct visual inspection when the urethra is distended with water has been described in these columns. He here gives eight views of the enlarged prostate seen by this means, the findings explaining the mechanism of retention of urine and the easiest way of restoring permeability. A needle or small knife can be inserted in the protuberant lobe of the prostate and the resulting shriveling opens the passage for the urine. Not the depth of the incision but its being carried throughout the entire length of the lobe is the main factor in the success. This method of treating enlarged prostate is indicated only in the early stages and does not attempt to compete with prostatectomy.

86. Electric Apparatus for Local Application of Heat.—The apparatus is shaped like a drum but opens sideways into two parts, each half containing three incandescent electric lights. The opened drum fits over the shoulder, leg or any part desired and the heat can be graduated at will.

89. Antistreptococcus Serum.—Aronson has been experimenting on monkeys, mice and other animals with antistreptococcus serum. Among the results obtained he mentions success in saving monkeys by means of immune horse serum from the effects of streptococcus peritonitis, otherwise fatal in eighteen hours at latest. He urges the authorities to make arrangements for further studies of this kind in the tropics where the anthropoid apes can be procured at less expense for research on serum prophylaxis and treatment of tuberculosis, leprosy, syphilis and cancer, besides the streptococcus affections.

93. Gout and Rheumatism.—His emphasizes the frequency of groups of symptoms in gout which certainly have no connection with uric acid, mentioning among them dyspepsia, skin diseases, myalgia and neuralgia, arteriosclerosis and granular atrophy of the kidney. These and other phenomena observed suggest that the disturbance in the purin metabolism is not the true essence of gout but is merely one symptom of a more general disturbance. A number of cases encountered in the last few months confirm his idea that in rheumatism, aside from all the cases with known or probable etiology, such as trauma, inflammation, acute rheumatism and infections, there are a large number of cases in which the arthritis must be regarded as the manifestation of some general cause not localized in the joints. This applies particularly to Heberden's nodes, whose connection with gout and diabetes has long been known, although they may develop without either. This characteristic form of arthritis is so unmistakably independent of external causes that some endogenous injury must be accepted for all cases. Some typical examples are related of the many different ways in which chronic arthritis may be connected with an endogenous or familial predisposition to disease; they also demonstrate its close connection with gout. The disturbance in the purin metabolism is peculiar to gout and has nothing to do with chronic arthritis. It is important to differentiate the two, and Roentgen ex-

amination may aid, especially when the joints are deformed; gouty tophi cast no shadow. In dubious cases the criterion is the elimination of purin or examination of the blood for uric acid after four or five days of purin-free food. This differentiation is important on the practical grounds that severe chronic arthritis induces a tendency to cachexia and phthisis. It is purposeless and harmful to restrict such patients to a purin-free diet. Restriction to a milk-vegetable diet is imperative only in case of certain gout, or when the arthritis develops with other signs of an inherited taint. The gouty diathesis is liable to manifest itself in some other form than defective uric acid metabolism, while certain non-gouty forms of chronic arthritis may develop on a predisposing diathesis although the purin metabolism may not be disturbed.

94. The Therapeutic Action of Fibrin.—In this communication from Bier's clinic Bergel relates experiments which show that fibrin plays in the body the part of a protecting and healing substance. It possesses leucotactic, hyperemic and fermentative properties while stimulating the production of granulations and connective tissue and checking the growth of bacteria. He says that it is the fibrin which stimulates wounds to heal, thrombi to become organized, transplanted tissue to heal into its new bed, and callus to form after a fracture. Fibrin supplied from without displays all these properties as in the natural processes, and hence he advises the local application of a sterile, durable, pulverized fibrin as a physiologic aid to promote the rational healing of wounds.

95. Serodiagnosis of Postconceptional Syphilis.—Wechselmann affirms as the conclusion of his research that the newborn require antisiphilitic treatment when a positive Wassermann reaction is obtained and that, in case of negative findings, the test should be repeated now and then. If the reaction gives the same response in both mother and child, she can be allowed to nurse it, while a negative reaction compels repeated clinical and serodiagnostic control. A child giving a negative response should not be nursed by the mother giving a positive response. He is convinced that syphilis may exist for years exclusively in the interior of the body without the slightest signs or symptoms to reveal its presence. This is particularly liable to occur in women infected by their husbands in a late phase of syphilis, the virus probably being much attenuated. The complement-fixation test is the only means at our disposal that allows us insight into these occult cases.

97. Cerebrospinal Fluid in Postdiphtheric Paralysis.—Roemheld reports a case in which diphtheria in a merchant of 30 was followed by paralysis involving the muscles of accommodation, the palate and the legs. The cerebrospinal fluid contained an abnormal proportion of albumin which gradually subsided as the patient improved under treatment. In another case in a child the paralysis had subsided but the patient became imbecile; the proportion of albumin in the fluid at 18 was exceptionally large. These findings suggest that prolonged postdiphtheric paralysis may be the result of changes in the central nervous system as well as of a peripheral neuritis.

99. Treatment of Pleuritic Effusion.—Fellner applied superheated air to one-half of the thorax in the effort to induce absorption of an effusion which had for months resisted all other measures. The heat was at first 80 and 100 C. (176 and 212 F.), increasing later to 120 and 140 (248 and 284 F.). The sittings were at first 15 and later 30 minutes long, given every second day at first, then for 2, 3, and 4 days at a time. Prompt benefit followed; after 35 applications all signs of inflammation had vanished and the patient felt better than for years.

- 107 Questions of Climate in Balneology. (Klimatische Fragen in der Balneologie.) Dove.

100. Effects on Circulation of Hydrotherapy.—Müller has studied the effects on the heart action of various hydrotherapeutic measures, both in health and disease. His conclusions show the physiologic bases for the action of hot, cold and carbonated baths. With failing compensation the blood pressure drops in response to cool carbonated baths, which thus do more harm than good. When the compensation is good the response is similar to that in health, and great benefit may be derived from these measures along the lines of this physiologic reaction.

101. Tuberculosis of the Kidneys.—Blum reviews the experiences at the Vienna polyclinic with tuberculosis of the kidneys, his conclusions all being in favor of radical surgical intervention. Even in the early cases there is absolutely no justification for internal medicinal, climatic, specific or physical therapy. They are only a waste of time, he asserts, and reduce the chances for a successful operation. The possibility of spontaneous recovery is so slight that it should not be taken into account at all.

102. Scopolamin-Morphin in Obstetrics.—This communication adds 600 more to the 1,000 cases of delivery in the scopolamin "twilight sleep" previously published from Krönig's clinic at Freiburg. The conclusions are about the same as those of Gauss in the former series. Measurement of the amount of blood lost in 497 cases showed an average of 382 gm., fully 95.16 per cent. of 571 deliveries being accompanied by merely moderate loss of blood. There was no morbidity in 536 cases, while in 17 there was some febrile disturbance of puerperal origin in 6, afebrile in 1, and non-puerperal in the 10 others, the total morbidity being 4.68 per cent. Of the 609 children, 7, that is 1.14 per cent., were still-born, while 10 were non-viable. About 5.14 per cent. of the 609 children (31) were in asphyxia and 9 of these children died within three days. In 2 cases death occurred from aspiration of amniotic fluid. Three children died between the third and ninth day, but 581 of the 588 children born alive left the clinic in good condition, that is, 98.8 per cent.

106. Simple Method of Reducing Dislocation of the Shoulder.—The forearm is held between the physician's thighs as he stands in front of the seated patient. The arm is held firm by the adductor muscles and strong pressure can thus be brought to bear as the physician pulls back while holding the shoulder with his hands. The downward pressure thus exerted overcomes the action of the antagonist muscles and stretches the capsule and ligaments until reduction is easily done. Schiehhold has applied this method in many cases during the last forty years and with satisfactory results. The chief advantage of this technic is that he can regulate, himself, the force of the traction exerted to the exact amount required for reduction, as he grasps the neck of the humerus with one hand and with the other presses the head into place, both hands being free for the manipulation of the joint. The only assistance required is some one to hold the patient firm in the chair, one arm around his neck and the other in the axilla. This technic allows rapid reduction of even old dislocations without anesthesia, assistance or apparatus.

- 114 *Treatment of Rupture of Uterus. (Zur Behandlung der Uterusruptur in Anschluss an sechs eigene Fälle.) G. Petren. Commenced in No. 3.

110. Operative Treatment of Retroflexion of the Uterus.—Stolz gives an illustrated description of his intraperitoneal method of shortening the round ligaments and compares it with similar technics that have been published. He has applied it in seven cases in the clinic with good results. Its principal feature is the intentional antelexion and elevation of the uterus by suture of the round ligaments slanting across the lower wall of the uterus. Movable backward displacement of the uterus was the indication for the operation in most of his cases.

111. "Anchor Incision" for Uterine Retrodisplacement.—Palm applies the term "anchor incision" to a curving transverse incision, with perpendicular median incision, for the second step of the Alexander operation. He has had occasion to operate by this technic in seven cases of complicated retroflexion with extensive and solid adhesions and other lesions requiring ovariectomy, myomectomy or other comparatively serious operation. Four of the patients have borne children since without disturbance, twins in one case in which the patient had had bilateral femoral hernia, prolapse of the vagina and inflamed adnexa on one side with two myomas. He adds that one idea is the same as that of Kreutzmann, published six months later than the description of Palm's first operation by this technic.

112. The Alexander-Adams Operation.—Lesse has applied this technic in 175 cases and expresses satisfaction with it, notwithstanding that there was recurrence in 2.5 per cent. of 83 women whose later history is known. Thirty-five of the women have passed through normal pregnancy since, including 7 who had the operation done to cure sterility. In 3 other cases of this kind conception has not occurred to date.

113. Remote Results of Conservative Treatment of Inflammation of the Adnexa.—Prochownick discusses the limitations for conservative treatment, on the basis of 160 patients thus treated between 1892 and 1905, and recently re-examined. When recurrence took place it was during the first three years in 95 per cent. of the cases and in the majority at the beginning of the second year. It seems evident, therefore, that three years is long enough to estimate the ultimate outcome of treatment; 55 per cent. of the women were cured by a single course and 15 per cent. by a second course, of from four to six weeks. The patients at first remain in bed, with local ice applications, changing to moist heat, then to superheated air or local electric light baths, with hot vaginal douches, sitz and full baths, the mercury colpeurynter for from two and a half to three hours every day, and a hard rubber stretching cylinder introduced at night to act on the indurations and cicatricial tissue in the pelvic connective tissue; general massage is begun as early as possible, and the patient is allowed gradually to get up. At four or five day intervals ichthyol glycerin or tannin glycerin is applied locally on gauze, never stronger than 5 per cent., and all other measures are omitted on the days of the local treatment and all measures during the menses. At the slightest rise in temperature—taken four times a day—the patient must stay in bed. Abscesses are opened and drained, into the vagina if possible. In 48 of the 160 cases the conservative measures proved ineffectual and surgical intervention was required. The improvement in the subjective symptoms under complete repose was in marked contrast in these 48 women to the persistence of the objective findings; the prognosis was particularly grave in the cases in which there was not even subjective improvement and the affection recurred more severe after the first course of conservative treatment. When the first course failed to show marked improvement, the second and third courses merely postponed the inevitable surgical intervention and rendered the conditions less favorable for it. He regards it as the greatest progress in gynecology that more than half of all the chronic inflammatory affections of the adnexa can be permanently cured with patience and simple measures.

but, on the other hand, it is important to recognize early the cases for which conservative measures are not adapted so that surgical intervention can be promptly applied.

114. Rupture of the Uterus.—In addition to the 6 personal cases described, Petren tabulates the details of 754 cases of rupture of the uterus which he has been able to find in the literature of the last thirty years. Of these 754 women, only 238 survived, including 140 out of 501 treated by conservative measures and 82 out of 174 by a laparotomy. The statistics to date are thus in favor of laparotomy in treating rupture of the uterus, the organ being removed as a rule, and always if there are signs of infection. The general practitioner hesitating to undertake such an extensive operation had better summon the specialist to the house or have the patient taken to the hospital, where this operation is no more dangerous than operation for ruptured extrauterine pregnancy. Laparotomy was done in 10 of the cases in the statistics after the patient had thus been sent to the hospital, and with successful outcome in 6.

116. Influence of Specific Treatment on Serodiagnosis of Syphilis.—In this communication from Neisser's clinic at Breslau the findings of the complement-fixation test as applied in 5,200 cases of syphilis are tabulated and compared. The findings were positive in inverse proportion to the number of intermittent courses of treatment that had been applied in the individual cases. This connection is seen most strikingly in the old latent cases; with a single course of treatment the positive and negative findings were each found in 50 per cent. of the cases while the findings were negative in 50 per cent. of the cases in which there had been eight or more courses of treatment. The more energetic the treatment the smaller the proportion of positive responses. This was observed even in cerebrospinal syphilis, negative results being obtained in 5 out of the 11 cases in which thorough treatment had been given: A single course of treatment does not seem to have much effect on the findings with the test, but the general impression is all in favor of the efficacy of thorough treatment in the first months and years after infection. After the disease has become once firmly lodged in the system the chances for complete cure seem to be much less. The drugs administered may not make their effect felt in the complement test until months afterward. In time we may be able to distinguish two groups of syphilitics, those with positive findings at first and then a constantly negative response later, showing that the disease has been actually stamped out, and those who respond positively all the time or intermittently, showing a peculiarly refractory form of the disease and the necessity for continued treatment. Until we have learned to classify patients thus beyond possibility of mistake, it is wisest to treat them as energetically and as early as possible after the diagnosis is once established, and to repeat the courses as energetically as possible during the first years after infection, regardless of the manifestation of symptoms or their absence.

119. Pancreatitis.—Dreesmann has observed six cases of acute and three of chronic pancreatitis confirmed by operation during the last year, and discusses the diagnosis and the imperative surgical treatment. He is convinced that many cases of supposed recurrence of gallstone trouble are in fact merely cases of pancreatitis. The pain is generally referred to the stomach region and is severe and persisting, usually spreading along the left side and up or down or sometimes localized in the region of the cecum; in one case it exactly simulated sciatica. The pain increases during digestion and movements, and there is tenderness in the stomach region or over the gall bladder and sometimes in the lumbar region. Syncope, collapse and cramps may be the first symptoms or large amounts of bile may be vomited. Fecal vomiting is rare, but the expression is characteristic, differing from the facies hippocratica as the complexion is grayer, possibly from loss or destruction of blood. In the 118 operations on record 8 patients died of the 40 treated by tamponing of the pancreas, and 53 after other operative measures, a total mortality of 55 per cent.

123. Etiology of Postoperative Complications in Lungs.—Lichtenberg reports two cases of croupous pneumonia occurring after herniotomy, confirming his conception as to the origin of this complication in an infectious embolism.

137. Restricted Localized Action of Drug.—Petrov reports extensive research on rabbits in which a drug was injected after the part of the body involved had been shut off by a constricting band from the rest of the circulation. The mode of diffusion of the drug was instructively studied on the rabbit ear injected in the marginal vein with a weak solution of a stain which could be seen diffusing through the tissues as the ear was held up to the light. The tint grew less intense in the vein in a minute or two and by the fifteenth to the twentieth minute the stain had diffused entirely through the surrounding tissue. This interval of twenty minutes suffices

for diffusion of the injected drug and nothing is gained by waiting longer. A stronger solution is no more toxic than a weaker concentration. It is possible that the stronger solution passes more completely through the vessel walls and enters into a more stable combination with the tissues so that it is not yielded up to the circulation so readily as the weaker solutions. Addition of adrenalin did not seem to reduce materially the toxic action of the drug injected, but the symptoms of intoxication were apparently a trifle milder than without the adrenalin.

138. Access to Base of Brain Through the Nasopharynx.—Löwe apologizes for adding another to the twenty-one methods on record for exposing the base of the brain, but he justifies his proposed technique by stating that it is much simpler than any of the others; only local anesthesia is required for it, and no incision is made in the face, while the nose is left intact. All that is necessary to have ample access to the optic chiasma, the hypophysis and the anterior pons region is to open up the sphenoidal sinus and this is easily done through the roof of the nasopharynx, pushing mucosa and periosteum apart, the incision in the median line, and opening a passage through the body of the sphenoid. Before the operation a strip of cambrie is passed through each nostril and out through the mouth and tied around the ears, thus holding the soft palate out of the way. The tongue is held down by a strip passed in through the pharyngotomy incision and out through the mouth, the ends tied tight together over the chin. The instruments used have to have rather longer handles than usual and be a little stronger to work at the depth required. He describes the technique in detail and mentions a number of anatomic points useful to bear in mind in operating in this region.

141. Treatment of Placenta Prævia.—Krönig protests against the rose-colored statements of various recent writers that hemorrhage from placenta prævia can be readily controlled by version or the metreurynter. To show the contrary, he summarizes the details of twenty cases of placenta prævia at the Freiburg clinic in which the women were under the most favorable conditions in regard to medical supervision in a clinic, asepsis, etc., from the start. Version arrested the hemorrhage during delivery in every instance without fail, but the metreurynter failed occasionally and can not be relied on. The chief danger in placenta prævia is from the recurrence of hemorrhage an hour or so after expulsion of the child or placenta, and the hemorrhage stops then only when the patient collapses so that the blood pressure drops too low for the blood to flow. The bleeding is from the isthmus, as a rule, which explains the failure of tamponing in these cases and the objection to the metreurynter as it stretches the isthmus still further. Four of the twenty patients bled to death and another succumbed to sepsis, and yet the conditions were exceptionally favorable for all. Those who survived suffered long from severe anemia. The more advanced the pregnancy the greater the tendency to hemorrhage. The conclusions from this series of cases are that the results of treatment of placenta prævia are so disappointing by the present methods that it is incumbent on us to seek for improved methods of treatment. He has been looking over the records of the 34 cases of placenta prævia received at the clinic since 1904, in which the date of the first hemorrhage is

mentioned; in every instance a warning hemorrhage had occurred during the last few days or weeks before the childbirth. The physician summoned merely ordered the patients to bed and the hemorrhage stopped with the bed rest. These warning hemorrhages recurred three or more times before labor came on, and the physician would have had ample time to send the patient to the clinic if the warning of these premonitory hemorrhages had been heeded. The obstetrician is able to save the mother with contracted pelvis by perforation during delivery in the home, but with placenta prævia both mother and child succumb in 15 or 20 per cent. of the deliveries in private houses. Even in the clinics the mortality is still from 5 to 8 per cent. at the best.

143. Local Anesthesia for the Uterine Cervix.—Henrich reports favorable experiences at Freund's clinic at Strasburg with local injection of a solution of 1 part beta-eucain; 0.6 parts sodium chlorid; 8 parts of a 1 per thousand solution of adrenalin, and water to 100 parts. The fluid is injected at four points, directly into the cervix, using about 1 or 2 c.c. It renders the cervix absolutely insensible, doing away with reflex spasmodic contraction and allowing dilatation and incisions without resistance or pain.

147. Albuminuria in Aseptic Fever.—Lavagna's research on rabbits demonstrated that simple hyperpyrexia alone is unable to induce albuminuria. In infectious processes the albuminuria seems to be the result of the toxi-infection acting on the finer structure of the kidney.

148. Frontal Vein as Means of Identification.—Professor Tamassia of Padua suggests that the variations of the frontal vein from the median line are peculiarly individual and characteristic and might well be utilized as a means of anthropomorphic identification. The course of the vein is recorded on a diagram like an anchor, a curved line for the bottom of the brow with a dotted median line from the glabella to the center of the curved line.

THE RESISTANCE OF THE HUMAN BODY TO CANCER *

H. GIDEON WELLS, M.D.

CHICAGO

After many years of careful and painstaking work by the surgeons, during which the radical operative methods have been developed to a high degree of perfection, we are still forced to admit that as yet the results of surgical intervention in cancer are anything but satisfactory. The most skilful operators can claim at the best but about 40 per cent. of recoveries in cancer of the female breast,¹ while in cancer of the cervix of the uterus recovery without subsequent recurrence is an exceptional result of even the most radical pelvic operations. Martin² gives 10 to 20 per cent. of such patients free from recurrence after five years. Pylorectomy has but occasional isolated recoveries to its credit and even in the least malignant form, carcinoma of the skin of the face, recurrence follows in about 40 per cent., while with carcinoma of the lip success is even less common,³ and Butlin⁴ reports a three years' cure in but 31.4 per cent. of his operations for cancer of the tongue. Probably we have nearly reached the extent of our possible progress in the direction of operative skill, at least so far as extensiveness of removal of tissue is concerned, and consequently the surgeons feel that the only possible direction for improvement is in early diagnosis. Admittedly there is room for great improvement in this respect, and with the rapid bettering of the conditions of medical education it is to be hoped that soon a larger proportion of practicing physicians will be able to recognize even deeply hidden cancers at least as early as the best trained men now can. But while earlier diagnosis and operation in carcinoma will undoubtedly bring up the percentage of complete cures, yet even under the best of conditions the mortality will still be high. How often, if ever, can a surgeon feel certain after he has removed even the earliest cancer of the uterus or of the breast, that recurrence will not follow? Even with the relatively slow-growing and easily diagnosed carcinomas of the face and lips recurrence frequently follows early and radical operation; while with melanosarcoma of the chorioid or iris, which

is frequently diagnosed when extremely minute on account of the early effect on vision, operative removal of the entire eye almost never prevents the development of secondary tumors in other organs, although the primary growth may be smaller than a split pea when the eye is taken out. Therefore, no matter how skilful we may become in diagnosis, and however radical our operative procedures may be, malignant neoplasms will still remain a dreaded and fatal affliction for which some other cure than surgery must be sought. But in the face of the many years of failure in this research, the question forces itself on us, have we any right to expect that a specific cure for cancer ever will be found? Is there any good reason for hoping that a method of curative treatment can ever be devised, or must we be resigned to accept the best possible results of surgery as the only goal towards which we can direct our efforts?

While a few years ago the average pathologist expressed himself as very dubious as to the prospect, at the present time there seems to be growing a belief that the hope of a specific treatment for cancer is not unreasonable; not simply from the standpoint of a general optimism which believes that everything good is possible, but because of certain facts in the biology of tumor growth which afford a substantial basis for believing that malignant tumors are not essentially incurable.

If we wish to find a specific therapy for an infectious disease we have two methods available: Either we may stumble on a cure by purely empiric methods, as was done with malaria and syphilis, or we may study the manner in which the body defends itself against the disease, and endeavor to heighten, supplement, substitute or even to initiate this natural method. Perhaps we may consider as in a class by itself the method of therapeutics that is now being developed in Ehrlich's laboratory, in which by more or less empiric methods a substance is found that has some favorable influence on an infection, and then guided by experimental results this influence is enhanced by addition of various and sundry radicals to the nucleus furnished by the original substance. Likewise in the search for a specific therapy for cancer we have the same three methods available, since we must look on cancer as an infectious disease, whether we believe with some that it is due to invasion by a parasite coming from without, or accept the opinion that seems to be held by the majority of pathologists, namely, that in cancer the parasite is the cancer cell itself, and that no extraneous organism whatever is concerned in the disease.

Empiricism has had its chance for centuries without success, and although anything may happen, yet we can certainly have little reasonable hope for any results from this source. As for the synthetic method of Ehrlich, this is yet too young to hazard prophecies;

3. Meller's statistics show 50 per cent. of cancers of the head, neck and face free from recurrence three years after operation. (Ztschr. f. Krebsforsch., 1907, vi, 64.)

4. Butlin: Brit. Med. Jour., Jan. 2, 1909.

results that seem to be of value have been obtained with certain of the trypanosome infections; there is ground for hope that the long-desired substance which will kill bacteria without harming the host may eventually be found by this method, and therefore if cancer is due to extraneous parasites it may come under the influence of parasitocidal substances. This much can be said for these two possible sources of cures.

But at the present time we are inclined to believe that the most logical way to find a specific remedy for an infection is to learn how the body cures itself when natural recovery takes place, and then, if possible, to enhance these natural defenses of the body. Before we can do this in the case of cancer, however, we must first satisfy ourselves as to whether the body has any means of defense against malignant growths; for there is a wide-spread opinion that no such natural defense exists and that spontaneous healing can not or does not take place. My purpose in this paper is to point out the evidence that the human body does have some means of natural defense against cancer, which commonly appears to check all tumors to a certain extent, which sometimes impedes their progress greatly, and which very rarely indeed may entirely overcome the malignant growth and lead to complete healing.

It is through the establishment of these facts that we are entitled to hold a reasonable hope that malignant neoplasms will not necessarily always be incurable; and it is through study of the processes which come into play in this natural defense that we may look for the road to therapeutic progress.

We may start out at once with the assumption that no malignant neoplasm ever succeeds in growing to the extent to which its innate proliferative ability entitles it. Ehrlich has calculated from studies of the rate of growth in experimental mouse cancer that if a single cancer graft started proliferating at the usual rate observed in one of his experimental series, and if every descendant graft was implanted into other mice and the process repeated as fast as the tumor reached a size of 1 c.c., leaving out of consideration all difficulties in the way of space and nourishment, at the end of one year the total production of tumor tissue would form a mass, which, if cubical, would have an edge one thousand billion kilometers long and would require a ray of light 105 years to travel the length of one edge of the cube.⁵ Such unlimited proliferation would make short work of a mere man, but it can not occur if for no other reason than that the supply of nourishment is bound to be inadequate, and there is no danger that the fear expressed by a medical humorist will ever be realized, namely, that at this rate of growth of mouse cancer and the rapid multiplication of institutions for cancer research, there will soon be danger that all the available nitrogen will be fixed in the form of experimental tumors on mice. One of the commonest occurrences in malignant growths, especially in carcinoma, is necrosis or less extreme retrogressive changes, due to lack of blood supply, which in the main result either from the pressure of the peripheral parts of the growth shutting off the blood supply to the more central portions, or from the tumor cells growing away from their blood supply until they are insufficiently nourished, just as the surface epithelium of the body normally grows away from its supply until the surface cells die

and drop off.⁶ Again, the rate of growth of a tumor is very decidedly influenced by the nourishment of the patient as a whole; in young, well-nourished persons the rate of growth is usually rapid, and recurrence follows promptly upon operation; in the senile and in the diseased and feeble, tumors grow slowly, and at times seem to remain stationary. The patient suffering from cancer cachexia often lingers on and on with the tumor remaining practically stationary; the development of intercurrent infections notoriously impedes the progress of neoplasms; severe hemorrhages from cancers have been repeatedly observed to be followed by an improvement in the conditions of the growth and an abatement in the progress of the disease, and in the senile a cancer may scarcely influence the health and duration of life at all. On this same principle is based the treatment of inoperable cancer by ligating the vessels that supply it, and also the "hunger cure" of cancer that was once in vogue, not to mention medieval practices of phlebotomy and the production of chronic ulcerations on the extremities of cancer patients "to let the cancer humours escape." In general the rate of growth of cancer is in direct proportion to the nourishment and vitality of the patient, quite the opposite from the relation in the infectious diseases. This is a fact, it seems to me, which may well be advanced among the many arguments that are presented against the parasitic origin of cancer. These various nutritional impediments to tumor growth, while undoubtedly important in retarding the course of malignant disease, have little bearing on our subject of cancer therapy, since they represent entirely non-specific and purely adventitious influences. In the same category may be placed the influence of infection, which, when general, may impair the rate of tumor growth,⁷ and when local may destroy more or less of the tumor tissue, including a few isolated cases in which an entire growth is said to have been thus destroyed.

Of more interest to us in our search for natural means of defense are the instances in which malignant tumors show healing changes independent of such merely accidental influences as those cited above. These healing changes may consist of (1) spontaneous local inhibition or temporary retardation of growth, or (2) of retardation of recurrence after removal, or (3) of retrogression of secondary growths after removal of the primary tumor, or (4) of disappearance of portions of tumor tissue left at an incomplete palliative operation,

6. Since this article was written there has been published the very interesting lecture by Handley (*Brit. Med. Jour.*, March 6, 1909), on the "Natural Cure of Cancer." Handley's studies on the method of extension of cancer, which have been of such inestimable value in influencing surgical methods of treatment, have yielded some interesting results as to the healing processes that are constantly going on in every cancer. The permeation of lymphatics by cancer cells is followed normally by a process of fibrosis, and, in cases of cancer of the stomach, by the use of specific mucin stains, traces of the mucin left by destroyed cancer cells may be found in the fascia of the abdominal wall when nothing else whatever remains of the original cancer cells, thus showing how complete the local healing of cancer extension may be. Macroscopically, also, if one studies carefully from time to time the location of disseminating cancer, it may be found that many of the nodules disappear, while further away from the primary growth new nodules are springing up. Handley has come to the conclusion that "the progress of a cancer is normally accompanied by retrogressive or curative processes; that the recorded cases of natural repair of cancer, far from being anomalous and exceptional, merely illustrate more strikingly than usual the natural laws which govern every case of the disease." He also propounds the following as a law of cancerous growths: "Every aggregation of carcinoma cells has a definite life-cycle, and, after increasing in size for a varying period and at a varying rate, tends spontaneously to undergo degenerative and fibrotic changes. These changes extend from the center of the mass centrifugally to its periphery, lead to its shrinkage, and terminate in the replacement of the aggregation of cancer cells by a fibrous scar." Handley's account of the processes of cancer extension should be read by everyone who is interested in understanding the principles of cancer growth.

7. For review of relation of erysipelas to cancer see Bologna: *Ztschr. f. Krebsforsch.*, 1908, iv, 261.

5. Ehrlich: *Berl. klin. Wchnschr.*, 1905, xlii, 873.

or even (5) of spontaneous healing of a primary tumor without any operative intervention whatever. Cases and discussions purporting to illustrate all these different degrees of healing changes may be found reported in many places, and I shall not attempt to compile here the entire literature of the subject, but shall only refer to such instances as apply conveniently to the topic under consideration.

Total healing without operative interference of any kind, and without recurrence, is practically unknown. This does not necessarily mean, however, that such a thing does not occasionally occur, for it can be readily understood that a small malignant tumor coming under the observation of a physician competent to diagnose it would almost certainly be removed, while patients with tumors more advanced, in which operation can not be undertaken, can not be expected to recover spontaneously. In favor of the possibility of such spontaneous healing without operation is the case reported by Senger⁸ in which a woman forty-two years of age developed a tumor opposite the stump of a molar tooth. The irritating stump was removed, and part of the tumor excised for microscopic examination, which revealed a carcinoma; nevertheless the remainder of the tumor gradually disappeared and no recurrence followed. Crosbie⁹ describes a similar case in a young man with an ulcerating lesion of the lower lip associated with an eczematous inflammation. Part of the ulcerated area was examined and pronounced carcinoma by the pathologist, and although the rest of the growth was but partially removed the entire process healed up leaving only a little cicatricial tissue.

These and other similar cases suggest that when cancer follows chronic trauma the defensive mechanism of the body may be able, in the early stages, to overcome the cancerous proliferation if only the irritant which stimulates the malignant growth is removed soon enough.

Mohr¹¹ has described a case of carcinoma of the mouth which arose at the site of a carious tooth, grew slowly and at the end of four years began to show involvement of the regional glands. After reaching a very serious condition it began to improve and at the end of two and one-half years seemed to have disappeared entirely. Unfortunately in this case no microscopic examination was made, but the clinical findings were apparently quite typical.

Rotter¹² records a case of malignant adenoma of the rectum that ran a malignant course for some time; the recurrent growth that developed after an incomplete removal later healed spontaneously. Death occurred some three years later from metastases that had formed in the right iliac bone, and the portion of the bowel at the place where the recurrence had been showed only smooth scar tissue.¹³

Von Hansemann¹⁴ saw a similar case which at first developed progressively, but by the end of eight years had disappeared entirely.

Mohr also has collected from the literature a few cases of healing of superficial carcinomas, of which he speaks as follows:

Complete healing may occur in rare cases through calcification of an epithelioma. A few rare instances of complete or almost complete calcification and spontaneous healing of epitheliomas have been reported by Förster, Denecke, Stieda, Linser and others. Förster, for example, observed an epithelioma, the development of which was checked by complete calcification of all elements. In Stieda's cases a sharply limited connective tissue capsule with greatly calcified alveoli was present. . . . According to some authors (Dubreuil, Butlin, Bowen) it happens that in rare cases superficial epitheliomas of the skin, especially rodent ulcer, may entirely cicatrize and atrophy. . . . According to Krebig, the epithelial tumors that appear in xeroderma are relatively benign; they may spontaneously become largely replaced by granulation tissue and partly or entirely heal.

Jacobsthal¹⁵ has described an interesting case of extensive spontaneous healing of a carcinoma of the skin of the temple of a man, aged 49, only a narrow zone of proliferating tumor cells persisting about the periphery. Here the healing seemed to be accomplished by the ensnaring and invasion of the cancer cell nests by fibrous tissue, much as Exner¹⁶ has described the processes of healing that take place in cancer under the influence of radium. Similar destruction of cancer tissue by overgrowth of elastic tissue has been observed by von Saar¹⁷ who found accidentally, while studying the effects of age on the mammary gland, a minute (*linsengross*) carcinoma which seemed to be undergoing strangulation by elastic tissue, and he states that, in general, epithelial growth in the mamma leads to a local hypertrophy of elastic fibers which sometimes results in the degeneration of the epithelial elements. As a rule, however, the elastic tissue disappears early and permanently from the tissues in the vicinity of advancing carcinomas of the skin.¹⁸

Martin¹⁹ records the only case of spontaneous healing of uterine cancer that occurred in his large experience, in the following words:

In the year 1872 a woman, 40 years old, was brought to me with a scirrhus ulcer of the cervix uteri and of the vault of the vagina. The diagnosis was established microscopically and an operation was refused. The symptoms were slight. Her family physician gave her condurango preparations. This physician reported to me after twenty-two years that the woman still lived; he himself has died since then, and I have not seen the patient again.

Besides this very unimposing array of more or less questionable cases in which carcinoma seems to have undergone spontaneous healing, there are several in which sarcomas and endotheliomas²⁰ have also disappeared, but as in these the question of differentiation from inflammatory growths is so often difficult they will not be discussed in detail. Frank J. Hall²¹ has also observed what appears to have been an example of spontaneous healing of a hypernephroma, which was found encapsulated and entirely necrotic within the substance of the kidney. The chorion epithelium tumors offer by far the largest number of cases of spontaneous healing, Gaylord and Clowes having collected seven, but these tumors seem to be in a class by themselves: at times benign, at times extraordinarily malignant, they not rarely start out with every evidence of malignancy, invading the surrounding tissues and possibly producing

even deeper metastases, and then for no evident reason their growth ceases and all signs of the tumor disappear.²²

The evidence concerning the healing of portions of carcinomas left after operation is far better than that offered as proof of spontaneous healing of growths on which no operation has been done. It has repeatedly happened that surgeons, having found tumors inoperable, have performed palliative operations, and assured the relatives that death would be only a matter of a few months, only to be surprised by having the patient live for years, in many instances dying not from the primary growth but from remote metastases when the original tumor had been quiescent or even retrogressive for a long time. In other cases the microscope has shown that the surgeon's incision in removing a tumor has passed through cancerous tissue, and yet, in spite of this, local recurrence had not taken place. Such happenings as these can be found scattered about in the literature, and they are undoubtedly far from rare; but often they have been misinterpreted, for the unexpectedly favorable outcome of the case has led to the suspicion in the first class of cases that the diagnosis may have been incorrect, and in the instances in which local recurrence has not appeared in spite of incomplete operation it has been thought that the remaining cancer cells were perhaps snared off by the ligature, or destroyed by a stitch abscess, or something of the kind. Apropos of the cases of improvement of primary growths which sometimes lead to withdrawal of the diagnosis of malignancy, I may recount the history of a patient in whom I was personally interested. In 1893 this patient, a man aged 63, was operated on for what seemed to be a recurrent appendicitis with abscess formation. On opening the abdomen, however, the supposed abscess was found to be a gelatinous mass of tissue, which was said by the operating surgeon to be a colloid cancer; the wound was closed except for drainage, and an unfavorable prognosis given. In spite of the development of a fecal fistula the condition of the patient began to improve after a short time, and a year after the first operation he underwent a second laparotomy for the purpose of closing the fistula. The surgeon who performed this operation found what was probably a small calcified mass from an old appendiceal abscess, attached to the bowel; although there were numerous adhesions he was able to remove this calcified plaque and closed the fistula. The patient made an excellent recovery, gained strength and weight, and resumed a very active life for a man of his years as stock raiser and farmer. Of course the first diagnosis of cancer was discarded and it was held up as a grave error on the part of the surgeon who had made it. It was not until 1905, twelve years after this first diagnosis had been made, that the patient began to be again troubled with abdominal symptoms, chiefly tympany with accompanying discomfort, in the course of a year developing into severe attacks of intestinal obstruction that eventually required operation for the relief of the obstruction. An extensive colloid carcinoma involving the abdominal viscera was found, apparently beginning in the vicinity of the cecum where there was a large tumor mass; smaller growths were found everywhere in the omentum, mesentery, and in the wall of the intestine. An anastomosis of the ileum to the colon was made to

relieve the obstruction caused by the large mass in the cecum, but the patient, aged 76, lived but a few days.

In this case it is impossible to learn further details about the first two operations, for the reason that the patient, although given up as the victim of an inoperable cancer of the cecum, outlived by several years the three surgeons in whose charge he was. Therefore I do not know whether the original diagnosis was confirmed by the microscope or not; but there can be little doubt that it was correct, for the operator was a surgeon of considerable experience and he defended his diagnosis with great positiveness, stating that there could be no doubt that the patient had a colloid carcinoma of the cecal region, which was in an inoperable condition. Apparently, following the operation the primary growth subsided rapidly, so that a year later another surgeon noticed nothing but abundant adhesions and a diseased and calcified appendix from which had resulted a fecal fistula; not until some eleven years after this second operation had the growth developed enough to cause symptoms. Its colloid nature, and its evident origin in or near the cecum, substantiate the long discredited diagnosis at the time of first operation.

Czerny²³ discoursed interestingly on this topic at the conference for the investigation of cancer in 1907, recounting various instances from his own rich experience and from the literature. He speaks of intestinal cancers as being especially likely to show the late return after palliative operation, as in the above case, recounting the following instances in his own practice:

A physician came to him for operation for a rectal carcinoma, and the carcinoma, together with a cancerous inguinal gland, was removed; yet after this obviously incomplete operation the patient was able to resume practice for seven years, and then died of a diffuse recurrence in the peritoneum.

A woman was operated on for a large carcinoma of the sigmoid flexure, of at least two years' duration, which was adherent to a loop of the small intestine. Although this certainly was not completely removed, yet after four years she was still free from evidences of recurrence.

In another case of resection of a carcinomatous sigmoid flexure the pathologist found that the line of incision had passed through cancer tissue, and yet five years later the patient showed no signs of recurrence.

He also referred to the frequent observation that after a palliative gastrostomy an esophageal cancer may so improve that swallowing again becomes possible, and to the decrease in size of inoperable rectal carcinomas which may follow colostomy, so that they sometimes become operable. These instances are probably related to the cases described previously in which removal of local irritation has been followed by retrogression of cancers (cases of Senger, Mohr, Proescher). Likewise after gastroenterostomy inoperable carcinomas of the stomach sometimes improve greatly, and Dancel has collected from the records of Czerny's clinic no less than eleven cases in which after gastroenterostomy for inoperable cancer the patient has been found to be well from two to fourteen years later. Although the possibility of incorrect diagnosis in these cases exists, since no microscopic examination was made, yet it is not often that a surgeon of Czerny's experience fails to recognize a cancer that is exposed to direct examination. There is also Beck's case, reported by Petersen and Colmers.²⁴

which seems to be beyond criticism. A colloid cancer of the pylorus was resected, but several cancerous glands were left behind along the lesser curvature; that they were cancerous was shown conclusively by the fact that a few which were removed were found to be involved. Three years later the patient was operated on for an umbilical hernia, and examination of the stomach showed no signs of local recurrence or of cancerous glands. One-half year later the patient died from intestinal obstruction, and at autopsy the only cancer found was a metastasis in the center of a uterine myoma and another in the sigmoid flexure; the cancerous lymph glands left behind at the time of operation had disappeared, and there was no recurrence in the stomach.

Gould²⁵ describes an interesting case in which two years after removal of a typical scirrhus carcinoma of the breast, the axillary glands became enlarged and were removed, only to be followed two years later by extensive recurrence in the scar, development of dyspnea, and later apparent involvement of the axillary and cervical glands, the left femur and right lung. Nevertheless these various recurrences and metastases subsided later, after the woman had been desperately sick for some time, and health was largely restored with none of the palpable tumors remaining. Even the crippled femur became repaired enough so that the patient could walk on it. Osler, Vulpian and others have reported similar cases.

Lomer²⁶ has made an extensive compilation of the cases in which palliative operations on cancer of the uterus have been followed by freedom from local recurrence for two years or more, and collected reports of 213 cases of this kind. Although he accepts cases that a less enthusiastic partisan might not consider well substantiated (notably ninety recoveries claimed by one American author), yet undoubtedly there are many of these reports that are correct, and there seems to be a remarkably large proportion of success among the cases persistently treated for each recurrence with the actual cautery, a point on which Czerny seems to agree. Perhaps the best authenticated of these is the one reported by Ziemssen, who examined at autopsy the body of a woman who had been operated on seventeen years before death for uterine carcinoma; local recurrence had developed after the operation, which was treated by cauterization, and yet no signs of malignant growth were found at the autopsy. Lomer himself had a patient who showed no evidences of recurrence ten years after an incomplete operation for carcinoma of the uterus. More recently Weindler²⁷ reports three cases of recovery for over five years of patients with inoperable cancer of the uterus treated by local cauterization.

Fleischmann²⁸ also has observed three cases in which, in spite of apparently very incomplete extirpation of uterine carcinoma there was no recurrence eleven, ten and eight years after the operation. On the other hand, so experienced an operator as Martin,²⁹ who has similarly treated inoperable uterine cancers by local cauterization, has had in his Greifswald clinic but one such patient live as long as twenty-three and one-half months, and one four and one-half years; 70 per cent. died in the first year.

There are numerous other isolated instances³⁰ indicating more or less healing of incompletely removed carcinomas, not to mention an even greater number of sarcomas, among which the giant cell sarcoma of bone especially may not recur after mere local curetting and other conservative methods, as Bloodgood,³¹ in particular, has emphasized. Of the other forms of sarcoma, lymphosarcoma seems most likely to show retrogressive and latent periods,³² but here especially errors of diagnosis are easily made.

From the evidence in these cases it would seem that in some rare instances the local forces, whatever they may be, which hold in check a malignant tumor, may succeed in overcoming it entirely, especially in certain cases when part of the tumor is removed. Ehrlich³³ has advanced an idea, as the outcome of his experiences with the transplantable cancer in mice, which may account for some of these cases. Observing that after an implanted cancer has once begun to grow vigorously it is almost impossible to plant another graft successfully elsewhere in the same animal, he suggests that some peculiar foodstuffs which exist in limited amount in the body may be necessary for cancer growth, and that when cells with a high avidity for this substance are actively growing they may accumulate all that is available and leave none for newly implanted cells.³⁴ Such immunity to inoculation is referred to as "atreptic" by Ehrlich. This hypothesis reminds one of the "exhaustion theory" of immunity advanced by Pasteur, and may seem rather fanciful, but it illustrates a general principle which often manifests itself, namely, that when a tumor produces abundant and vigorous metastatic growths the primary growth may sometimes cease active increase, and may even regress to a considerable extent. An interesting case in point is reported by Freeman,³⁵ as follows: A man aged 35 years, had a small indurated, crusted sore on the right side of the lip, which persisted for about one year, and then disappeared leaving a small scar. Less than one year later, and nearly two years from the beginning of the disease on the lip, a glandular swelling was observed in the right submaxillary region which was removed after about nine or ten months later; local recurrence took place and developed rapidly until a fatal carcinoma of the neck and face caused death. This growth, which apparently came from the submaxillary glands, was a squamous-celled carcinoma, indicating that the growth which had disappeared from the lower lip was a primary carcinoma.

Jacobsthal³⁶ mentions a very similar case in which a patient with carcinomatous submaxillary glands showed no other primary growth than a healed scar on the lower lip, where an ulcer had been which healed three-fourths of a year previously.

Seven cases of cancer of the breast, in which the primary growth slowly decreased until it had almost entirely disappeared, while at the same time secondary growths were appearing, are cited by Williams.³⁷ In all these the secondary growths proved fatal, although

at the time of death there remained practically nothing of the tumor in the breast, which might be considered as a form of atreptic process, the secondary growth withdrawing all the suitable nutriment from the primary growth. Osler and others have described similar examples of this sort of retrogression of primary tumors.

Another set of cases to which I particularly wish to refer are those in which operative removal of the primary growth leads to disappearance of, or healing changes in, the already present secondary growths. The case of Beck, cited above, is one of this sort, and there are others in the literature. I have had the good fortune to study a remarkably clear case of this type, thanks to the kindness of Dr. Alexander Harvey, in whose practice it occurred, and who has supplied me with his notes on the case.

History.—The patient was a woman, about 40 years of age, who had previously been operated on for the purpose of performing a ventrofixation of the uterus. In December, 1905, she complained of neuralgic pains in the facial, cervical, intercostal and sciatic nerves; on examination a tumor was found in the left breast, which was removed by operation on Dec. 20, 1905. After the operation there was considerable pain in the left arm and cervical region, and in the operation

Fig. 1.—Gross appearance of the liver. The depressed scars near the lower edge of the right lobe and on the anterior surface of the left lobe are the sites of islands of contracted scar tissue, which have replaced almost totally the tumor metastases that had formed here.

wound; these pains continued for the following eighteen months, although until nearly the end of this time her general health was good. In March, 1907, the patient reported suffering with severe occipital headache, loss of 20 pounds in weight, and polyuria. The urine showed a few hyaline and granular casts and a trace of albumin, specific gravity, 1.003, total amount in twenty-four hours as high as 90 ounces, but without the presence of sugar. She suffered from insomnia, severe headaches that could not be controlled by medication, and periodic vomiting; interstitial nephritis was suspected. Later the patient developed slight coma, with ammoniacal breath, dry skin, accentuated second aortic sound. She was removed to the Baptist Hospital, where she died in coma that had lasted two days, with several minor convulsions just preceding death, which occurred on June 15, 1907.

Autopsy.—The body was slender, but not emaciated. The left mammary gland was the site of a scar, which extended into the axilla, but there was still enough fatty tissue present to preserve the outline of a fairly developed breast. There could be found no induration about this scar, and no signs of tumor tissue could be found by dissecting up the tissue beneath the scar. The axillary glands were not enlarged, and the right breast was normal. In the abdominal cavity the uterus was found adherent to the scar of a median laparotomy wound, and attached to it by a silkworm-gut suture. The left tube and ovary were missing, and about one-fourth of the right ovary only remained, with the normal right tube. In the

lower end of the ileum was a hard white nodule, about 5 mm. in diameter, situated in the wall of the bowel 50 cm. above the ileocecal valve; the mucosa was not ulcerated over this nodule. In the mesentery of the upper jejunum were found about a dozen indurated lymph glands, containing an abundance of firm white tissue, and averaging about 3 mm. in diameter; there was also one hard and slightly enlarged retropancreatic lymph gland. The lower retroperitoneal lymph glands were not enlarged. The thoracic viscera showed no similar nodules or other changes of interest. The liver was found to be slightly smaller than normal, and dark in color. Just above the gall-bladder notch was a striking area of depression, due to a wide white scar several millimeters beneath the surface of the liver; the margins of this scar consisted of a narrow zone of what seemed to be tumor tissue infiltrating the liver for a short distance, and giving it a whitish appearance. In the anterior surface of the left lobe were two similar areas near together, one 15 mm. in diameter, the other 25 mm. (Fig. 1). In the stomach there were no evidences of carcinoma, but beneath the serosa, especially in the pyloric region, were numerous small subserous nodules, white and the size of a pin-head. The pancreas and right adrenal showed no changes, but the left adrenal was firm, white on the cut surface, and in the middle was a small nodular indurated area. The kidneys showed no gross changes, and there were no other findings of interest, except the presence of a few gallstones. Unfortunately the brain and meninges could not be examined.

Anatomic Diagnosis.—Old amputation of left breast; secondary carcinoma nodules, with fibrotic changes in liver, mesenteric glands, adrenal and ileum; old laparotomy wound with adherent omentum; old ventral fixation of uterus with amputation of left ovary and tube and part of right ovary; slight congestion of liver, kidneys and spleen; adhesive fibrous pleuritis, edema of lungs; calcified nodule in lung; cholelithiasis.

Histologic Examination.—Mesenteric Lymph Glands: The largest, 3 to 5 mm. in diameter, had been almost entirely replaced by carcinoma cells and fibrous tissue, the latter predominating. In the main the tumor cells were much compressed between dense bands of fibrous tissue, had deep staining nuclei and little cytoplasm, and their arrangement was in long strands with a tendency to tubule formation when not too much compressed. In a few places about the edge there seemed to be invasion of previously uninvolved lymphatic tissue where the cancer cells were not compressed, but even here no mitotic nuclei could be found. There was no evidence of necrosis or of giant-cell formation. Some of the smaller glands showed isolated groups of cancer cells infiltrated by lymphoid cells; others showed small areas of hyaline substance, and still others had an overabundance of fibrous tissue, suggesting that possibly there might have been a period when cancer cells were present in these glands, but that they had been replaced by hyaline material and fibrous tissue.

Adrenal: This organ was extensively infiltrated with carcinoma cells, peculiar in that the adrenal tissue was merely replaced without alteration in the size or shape of the organ. Both cortex and medulla were involved, but the growth was checked by the capsule. In many places, especially near the center of the adrenal, there was an abundance of fibrous tissue compressing the carcinoma cells, which tended to be arranged in tubules and in the outer edges of the carcinoma was frequently found an extensive round-cell infiltration. Where the amount of fibrous tissue was least mitotic nuclei could occasionally be found; they were also present in tumor thrombi found in the larger vessels of the medulla. There seemed to be two periods of growth represented here; one in which the carcinoma cells were partly replaced by scar tissue, and one in which the growth was now active.

Nodule in Ileum: This consisted of fibrotic tumor tissue having its center in the submucous connective tissue, but infiltrating into the serosa and mucosa. In the latter region the cells seemed to be growing freely without much connective tissue about them, but everywhere else there was much fibrous tissue which compressed the cancer cells. Mitoses were very scanty. Eosinophiles were abundant in the mucosa.

Stomach: The subserous nodules described at the autopsy were found to be small, well developed lymph glands, located in the serosa, and showing no tumor cells.

Liver: (Figs. 2 and 3). The depressed scars were composed of a uniform mass of scar tissue, poor in vessels, and with only an occasional group of cancer cells at the edges. This scar tissue, devoid of cancer cells, measured about 15 mm. across, while the zone of activity proliferating cancer cells outside it measured about 2 to 3 mm. The scar tissue passed quite abruptly into the cancer tissue and gave the impression that the healing changes had been rather suddenly terminated and active proliferation had begun not long before death. The proliferating cells were in columns and tubules, showed many mitotic nuclei, and a moderate amount of round-cell infiltration, but the free margin seemed to be invading the liver tissue without inciting any considerable reaction.

To recapitulate this case, we have to do with a woman who remained in fair health for nearly eighteen months after the removal of a carcinoma of the breast, and without recurrence in the scar or in the regional glands. The patient died, after a brief illness, with symptoms resembling those of uremic coma and accompanied by polyuria, very probably from cerebral or meningeal metastases, although this could not be determined, as we were not permitted to examine the head. The condition of the secondary growths that were found in the adrenals, mesenteric glands, ileum, and liver, especially the latter, indicated very clearly that, although active proliferation had been going on just before death, yet there had been an interval in which healing changes had predominated, so that in the liver nearly all the cancer tissue had been replaced by scar tissue, causing cicatricial depressions in the liver such as are commonly found in syphilis. Apparently on removal of the primary tumor growth had been temporarily checked in the secondary nodules then existing, and healing processes had made away with almost all the cancer tissue in the metastases in the liver. It must be that the conditions obtaining in those cases in which deep-seated metastases first make themselves known many years after the removal of a tumor are similar to those observed in this case.

Cases of similar nature have been described by others, and even with complete healing of the metastases; of these one of the most striking is that of Schuchardt.³⁸ In a patient on whom he operated for advanced carcinoma of the stomach were found large numbers of metastases on the peritoneum. Two and one-half years later the patient died from pleuritis, and at autopsy nothing remained of the peritoneal metastases and there was no recurrence in the stomach. Unfortunately in this case no microscopic examination of the nodules

was made, therefore the possibility of a combination of gastric carcinoma and peritoneal tuberculosis cannot be excluded.

Roux³⁹ also had a similar case, in which at a resection of a gastric carcinoma general carcinosis of the diaphragm was found, yet three years later the patient was still in good health.

Graham⁴⁰ has reported a case from the Pathological Laboratory of Rush Medical College of a woman who was operated on in June, 1897, for scirrhus carcinoma of the breast, which showed no signs of recurrence. In 1903 she became sick with diabetes insipidus, and died on Nov. 8, 1903. At the autopsy there were found no evidences of local recurrence in the breast, but fibrous cancer nodules were found in the pleura, liver, pancreas and adrenals. These nodules were either entirely encapsulated with scar tissue, which also intersected the tumor tissue, and when not encapsulated with scar tissue the tumor nodules were surrounded with young granulation tissue. In addition to these features the presence of pseudo-giant cells, the appearance of atrophied and

necrotic epithelial cells in portions of some of the tumors, and the absence of mitotic figures all pointed to a healing process which had checked the growth of these tumor metastases, which must have been in existence since, over six years before, when the breast tumor was amputated.

These cases all seem to indicate very clearly that the primary growth exercises in some way an influence on the secondary growths. Very frequently the sequel of an operation on a primary tumor is the rapid spreading and increase in size of metastases, so that the removal of a slow-

ly growing scirrhus cancer may be followed in a few weeks by death from an enormously rapid and abundant development of secondary growths. On the other hand, it occasionally happens, as in the cases cited above, that after the removal of the primary tumor the secondary growths seem to lose their power of proliferation, so that they may either become entirely replaced by fibrous tissue, or they may retrogress for a time and then begin to take on renewed activity of growth, as in my own case. Undoubtedly many of the instances of late recurrence belong to this last class. Labhardt⁴¹ has collected and reviewed the records of many cases of late recurrence of carcinoma, and found that of 2,142 cases of mammary carcinoma with recurrence, in 3.7 per cent. recurrence followed at a period of over three years after operation, and of 257 recurrences of carcinoma of the rectum 9 per cent. were after the three-

Fig 2—Low-power view of a cross-section of the large mass of scar tissue above the gall-bladder notch. The large, light colored area represents the island of hyaline tissue which replaced the cancer growth. About this is a mass of vascular scar tissue and fibrous adhesions, not yet contracted

year limit, and 9 per cent. of 373 recurrences following 1,300 operations for lip and face carcinoma appeared after the third year. Hirsch⁴² found that of 371 cases of recurrence of mammary carcinoma after operation 109 (29.3 per cent.) appeared between the fifth and fourteenth years after operation. Bircher⁴³ found records of about fifteen cases in which recurrence was first observed after operation for mammary carcinoma during the second and third decennium, of which one was in the twenty-ninth year and another in the thirtieth year. Cameron⁴⁴ also describes a case in which recurrence was observed beneath the pectoral muscle twenty-seven years after amputation of the breast for cancer. In these cases it would seem that cancer cells must have lain dormant for all these years, perhaps undergoing partial replacement by connective tissue but with a few cells remaining viable to start up proliferation again when the necessary conditions were present. Such facts make us wonder if most of our operative cures of cancer may not depend on spontaneous retrogression of metastases present at the time of operation, rather than on the absence of such metastases, which we have always assumed must account for all successful results.

Just how the removal of the primary growth causes this inhibitive influence on existing metastases is an interesting problem. It may be imagined that the primary tumor supplies some element which either stimulates the secondary growths or so injures the normal tissues that the secondary growths are not impeded. As supporting the first hypothesis to some extent may be mentioned the observation of Leo Loeb⁴⁵ that pieces of benign tumors may be transplanted into another place in the same animal in which they have arisen, and remain alive throughout, whereas when implanted into a different animal of the same species they become necrotic in the center or throughout. Apparently an animal in which such a tumor exists has something in its blood or tissues that favors the growth of this tumor and of secondary growths of the same tumor. An adenoma of the mammary gland of a rat that was transplanted into another part of the body of the same rat was observed to enlarge simultaneously with the swelling of the mammary gland that accompanied a pregnancy. Here, it would seem, is evidence of a stimulus that may incite tumor cells to multiply, and which is, perhaps, different from the substances that merely permit the transplanted tumor cells to live.

A possible explanation of the retrogression of metastases after operation which I would suggest is

autoimmunization. During operative manipulation a considerable amount of cancer juice and cancer tissue is forced into the circulation; ordinarily, as we too frequently observe, this results in a rapid and wide-spread recurrence, but it may happen that under certain circumstances these cancer products stimulate the reactive forces of the organism and lead to an active immunization. In support of the view that such immunization by cancer products is possible I would recount the very important case described by Mackay.⁴⁶ The patient, a woman of 37, was operated on for a scirrhus carcinoma of the breast, but recurrence after thirteen months was so extensive that operation was impossible. Twenty-one months after the operation there developed a bilateral pleurisy with large amounts of bloody effusion, apparently carcinomatous, and by the end of four months the patient seemed to be almost in extremis; suddenly the fluid in the chest cavity began to subside, coincident with which the patient's general condition improved rapidly, and the recurrences, so far as they were visible, disappeared in a remarkable way. This

disappearance is described (in a personal letter) as follows: "I described the changes as if the tumors had withered. A closer description would be to say that it looked as if the tumors had dissolved, and so dissolved, had become absorbed, leaving nothing but the covering of skin." Apparently the serum from the cancerous pleura, on being absorbed, either itself attacked the existing growths, or else, which seems to me more probable, it stimulated the resisting powers of the organism and led to

the development of cytolytins for the cancer cells which caused the rapid retrogression of the cancer tissue.* Ribbert⁴⁷ has reached a similar conclusion from his studies of the local reaction that occurs about carcinomas. In the early stages of the growth of a carcinoma the surrounding connective tissue is frequently stimulated to proliferate, so that the growth is at first walled off; later this reactive proliferation becomes less and less until it ceases entirely, and the carcinoma then advances unimpeded. Therefore, he thinks that in the case of spontaneously developing tumors there is no process of immunization, but rather the development of habituation of the tissues to the tumor, and the only prospect of immunization con-

Fig. 3.—Higher-power view of the junction of the hyaline scar tissue and vascular, cellular scar tissue. No cancer cells whatever are present in this scar tissue.

46. Brit. Med. Jour., July 20, 1907, p. 138.

* Dr. Mackay informs me by letter that his patient lived only a few months after this fortunate relief from her symptoms. He says: "My patient, I am sorry to say, died some five weeks after I had read my paper. (This would make the day of death about fourteen weeks after the events referred to.) She had gone through a very great amount of suffering under circumstances of excessive mental strain, and she died of exhaustion. So far as we could make out clinically the disease had absolutely left her. Whether, if she had lived, it would have recurred, is another matter."

sists in the sudden overwhelming of the organism with cancer substance which would stimulate an energetic production of antibodies, just as appears to have occurred in Mackay's case. Ribbert suggests that possibly injection of extracts of a cancer immediately after its removal by operation might induce an active immunity sufficient to destroy hidden metastases and cells left behind in the operation; a suggestion, which, in the light of the observations recorded above, seems well worthy of trial.

Finally, as another source of evidence of resistance of the body to malignant growths, may be mentioned the conditions under which metastases are formed. There seems to be prevalent an impression that the escape of cancer cells from the primary growth necessarily means the formation of secondary growth where these cells lodge, which is, fortunately, very far from the truth. In all probability only an extremely small proportion of the tumor cells that become scattered about the body ever succeed in multiplying, for otherwise nearly every malignant tumor would develop metastatic secondaries almost at its very start. It is by no means uncommon, for example, to find a hypernephroma growing into the renal vein as a soft friable tumor thrombus, from which cells must be continually breaking away, yet without having produced metastases. In primary carcinomas of the liver there have frequently been found hepatic veins containing tumor thrombi, and yet no secondary growths could be found in the lungs or elsewhere. Furthermore, we have a very excellent example of local susceptibility and local resistance to tumor growth in the well-known tendency of chorioidal melanosarcoma to produce metastases chiefly in the liver. The cells which escape from the primary growth in the eye must first pass through the lungs, and then be distributed all over the body in the systemic blood, of which the liver gets only a relatively small part through the hepatic artery besides what has passed through another capillary filter in the intestines and entered the portal vein; yet not infrequently in such cases the liver is found riddled or solidly infiltrated with melanosarcoma while the lungs and the rest of the body are almost entirely free from metastases. Evidently many tumor cells which have been lodged in the lungs and other tissues of the body must have been destroyed, while those that lodged in the liver found a fertile soil or a lack of local resistance. Other examples of this sort of local immunity could be cited in great variety.

Cohnheim, indeed, believed that the entire matter of metastatic growths, and, by the same token, the entire malignancy of cancer, depended, not on any peculiarity of the cancer cells, but on the degree of local power to destroy these cells. This view was based on his experiments with periosteum, which, when injected intravenously in small fragments, lodged in the lungs and formed by proliferation nodules of bone; but after a short time these nodules became absorbed. Lubarsch believes that the local resistance to tumor growth is much modified by the poisons which are secreted by the primary growth. M. B. Schmidt⁴⁸ has shown that by careful examination of the lungs of patients dying from abdominal cancer, emboli of cancer cells may be frequently found, (in fifteen of his forty-one cases) showing all stages of disintegration or organization, and others have repeatedly observed the same thing in mouse cancers. Similarly, degenerating cancer cells may be found in non-cancerous regional lymph glands of pa-

tients with cancers, or in the lymph sinuses about the glands, while hyaline and other degenerative changes may be found in a large proportion of such glands even when there is no bacterial infection to which they might be ascribed.⁴⁹ On account of these facts Lubarsch⁵⁰ suggests that cancer cells must first be repeatedly set free and destroyed in the regional glands until the poisonous materials thus liberated have so overcome the cells of the glands that they can no longer successfully resist the cancer cells. Similarly the regional glands, and also more remote tissues, may be prepared for invasion by cancer cells through the action of injurious materials discharged from the primary tumor. As Petersen expresses it, carcinoma cells can not flourish at once in remote tissues, because the soil is not fertile for them; they can grow only in soil that has been first thoroughly "manured" (*gedüngt*) with epithelial toxin brought by the lymph stream.

In any case, from the behavior of secondary growths after their formation as well as from the conditions that are necessary in order that secondary growths may occur, we obtain evidence that the tissues or the body fluids are enabled to defend the body to a very considerable extent against the cells of malignant tumors. The mechanism of this defense is not understood. One thinks at once of cytolysis, knowing that immunization to any given type of cells seems to lead to the production or more or less (generally less) specific cytolytic substances. In the cases in which healing changes have been studied, however, there have not been found good evidences of cytolytic changes, and Gaylord and Clowes state that there is no histologic evidence of cytolytic action in experimental tumors of mice undergoing spontaneous recovery. Sometimes the fundamental change seems to be a loss of the proliferative power of the cancer cells, so that the surrounding proliferating connective tissue now grows more rapidly than the cancer cells, strangling and destroying the latter through starvation. Becher, Schwartz, Petersen, and others have considered that in the healing of superficial carcinomas phagocytic giant cells are active destructive agents, but Borrmann,⁵¹ after a study of 265 cutaneous carcinomas, concludes that these giant cells attack only hornified and dead epithelial cells, and never the living, proliferating cells. On the whole the evidence seems to be in favor of the view that it is simply a decrease in proliferative power that leads to the spontaneous healing or to long periods of latency. Gaylord and Clowes conclude from the histologic findings in tumors that are undergoing resolution either spontaneously or under the influence of x-rays, that it seems plausible "that both the x-ray and the immune forces in spontaneous retrogression act in opposition to some stimulus which causes the limitless proliferation of the cancer cell." One can imagine a lack of the hypothetical *attractins* which B. Fischer's⁵² experiments have suggested act as stimulants to epithelial proliferation, or, possibly, as Graham has mentioned, *anti-attractins* may be formed. Certainly it is fundamentally important that this mechanism of defense should be most thoroughly worked out, for in it lies what seems at the present time to be the key to the solution of the problem of the specific therapy of cancer.

49. Fromme (Ztschr. f. Krebsforsch., 1907, v. 39) considers that mast cells play an important part in the defense of the lymph glands against cancer.

Just now our chief hope lies in the experimental work that is being done in numerous laboratories with the transplantable tumors of the lower animals. Not infrequently more or less retrogressive changes occur in these experimentally produced tumors, sometimes leading to definite healing of the new growths. Gaylord and Clowes⁵³ have observed healing of implantation tumors of mice that had begun to grow, in no less than 101 of 711 inoculations, but of these in only 11 had the tumor reached a diameter of 1 cm. or more. Other experimenters have not observed healing of successful grafts in nearly so large a proportion of their cases. It is well known that animals are immune to the majority of tumors with which inoculation is attempted, and even with the most readily transplanted tumors a considerable proportion of the inoculated animals do not develop tumors, indicating a very high degree of natural resistance. Also, susceptible animals in which inoculated tumors are growing rapidly are usually immune to inoculations.

But besides this natural, congenital immunity it has been found possible to obtain a varying degree of acquired immunity, both active and passive, in experimental animals. This fact offers us certainly the greatest encouragement in our search for means of checking malignant growth, and the evidence so far collected may be summarized briefly as follows:⁵⁴ Immunization against transplantable tumors was first demonstrated in mice by Jensen, in dogs by Stickler, and in rats by Leo Loeb. It was found that animals which had recovered spontaneously from transplanted tumors were quite immune to subsequent implantations of tumors, and that they might also be made immune without having to be actually infected with tumor growths. Stickler found that living tumor cells (sarcoma in dogs) injected directly into the circulating blood do not give rise to tumor growth, but, on the other hand, render the animal immune to subsequent inoculation. Ehrlich rendered mice immune to transplantable carcinoma by previous injection of benign mouse tumors, while Bashford found that the same result could be obtained with repeated injections of mouse blood, and Schöne immunized successfully by repeated injections of mouse embryos and various tissues of mature mice. On the other hand, immunity can not be produced by injection of tumor cells killed by chloroform, by heat or by cold.

Apolant⁵⁵ has also observed a form of healing of mice carcinoma that has never been observed in human carcinoma, namely, reversion of typical carcinoma to a benign adenomatous structure.⁵⁶ The change of adenomas and other benign tumors in man into malignant tumors has been observed frequently enough, but never the reverse change from malignancy to benignancy. This phenomenon occurred in experimental cancer only in animals that had previously been partially immunized against mouse carcinoma, which would seem to indicate that the resistance of the organism determines the nature of a tumor, just as the same factor seems to determine the starting of the new growths.

Passive immunity seems as yet not to have been so successfully produced as active immunity, nevertheless

there is evidence that the blood of animals spontaneously recovering from tumors may sometimes cause retrogression and even healing of tumors in inoculated animals, as well as render animals more or less resistant against implantation of tumors.

Also we have the "atreptic" immunity of Ehrlich, which has been previously mentioned, the fundamental manifestation being that animals with rapidly growing malignant tumors show themselves absolutely or relatively immune to subsequent inoculation with tumor tissue in some other part of the body,⁵⁷ an observation which has not been altogether confirmed by other investigators. Gay⁵⁸ has observed a somewhat related phenomenon in rats with transplantation tumors. In the strain of tumors studied by him there seems to be a "premetastatic period" of about thirty days, during which period only could evidence of the presence of antibodies for the tumor tissue be found by the fixation test. If during this premetastatic period, while the animal is still able to react to the implanted tumor by forming antibodies, a second implantation is attempted, in many cases not only does the second tumor fail to grow (atreptic immunity of Ehrlich), but the first tumor may disappear entirely or retrogress and undergo fibrosis.

Such observations accumulating within the few years during which systematic investigations of tumor transplantation have been in progress, give much hope that eventually something may be done for the cancer patient besides radical operation. How much we are entitled to transfer results of experiments with the transplantable tumors of lower animals to our pathology of human cancer is still a debatable question, but I trust that the human cases that I have collected and discussed will indicate that there also exist in man natural forces that tend to cause healing of malignant tumors, and that the possibility of augmenting these forces is before us and should encourage us to constant effort toward this end.

A Plea for a Wider and Better Extension of the Knowledge of Sanitary Science.—W. P. Mason in *Science*, April 23, 1909. says that this has been called an age of hygiene. The statistics and records of health departments show that the reduction in the death rate, etc., in many of the contagious and infectious diseases, justify the term. Still, a better knowledge of sanitary science should be extended to all classes of people. The sanitary instruction received in the schools is too often of an inferior quality, and there is too little of it given. Militia and army officers and all men who have charge of large bands of laborers should have enough knowledge of sanitary science to enable them to protect not only their own men, but also the communities in the neighborhood of their camps, from contagion and epidemics. "Of all the members of a community the physicians are the ones towards whom we most quickly look for instruction in matters sanitary;" then "it is pertinent to inquire if the medical schools provide such instruction as will place their graduates in position to properly meet their double responsibility. Such a question must too often be answered in the negative." Likewise, trained nurses are too often lacking in sanitary information. Too few of them know "why corrosive sublimate is not uniformly a good disinfectant for tuberculosis sputum." Sanitation in the matter of air and water is particularly considered. It is shown why careful supervision of water supply is demanded, and why more stress should be laid on the quality of the air we breathe. Although surprising, "the cold fact remains that bad air is responsible for more deaths than alcohol."

PRIMARY CARCINOMA OF THE LIVER

WITH REPORT OF A PATIENT WHO REMAINED WELL OVER TWO YEARS AFTER OPERATION

FRANK C. YEOMANS, M.D.

Assistant Surgeon to the New York Polyclinic Hospital
NEW YORK

Primary carcinoma of the liver is a rare affection. The literature on the subject consists mainly of reports of individual cases and consequent limited experience.

White¹ states that in 11,500 autopsies at Guy's Hospital during the years 1870-93, there were 11 (i. e., about 1 in 1,000) cases of primary carcinoma of the liver, and that but 7 such cases were reported in the Transactions of the Pathological Society of London during twenty sessions.

According to Eggel² of Munich, who has studied the subject exhaustively from the standpoint of pathology, primary carcinoma of the liver occurs about once in each 2,000 cases of all fatal ailments coming to autopsy. He tabulates 163 primary cases, of which 117 are de-

Photomicrograph of section of primary carcinoma of liver.

scribed microscopically, 100 being of liver-cell origin and 17 of the bile-duct variety. The others showed metastases or infiltration, malignant in character. Ewing³ affirms this classification and states that "primary carcinoma of the liver does not necessarily exhibit a single characteristic structure."

Contrary to formerly accepted views, Eggel's findings establish the frequency of metastases (66 per cent.) from primary hepatic carcinomata and shows their tendency to form tumor thrombi in large vessels. In his cases, metastases involved the following structures singly or in combination: veins (59 times), glands (38 times), lungs (17 times), gall bladder (7 times), kidneys (5 times), bones (4 times), peritoneum (4 times), spleen, pancreas and pleura (twice each), thyroid, esophagus and heart (once each).

William J. and Charles H. Mayo⁴ report that clin-

ically primary carcinoma of the liver "appears in several forms: (a) massive development, which involves a large section of the liver and has a well-marked line of differentiation from the sound tissue; (b) infiltrating; (c) nodular growth, usually one primary growth with secondary nodules." This corresponds to Eggel's macroscopic findings, the growth in 104, or 64.6 per cent., of his cases being of the nodular form, 37, or 23 per cent., of the massive type, and 20, or 12 per cent., of the diffuse variety.

ETIOLOGY

Its etiology is obscure. It seems to occur later in life in the primary than in the secondary growths. According to Eggel, the fifth decade is the period of predilection, but cases are recorded at all ages from the third to the seventy-sixth year. There was a history of hereditary carcinoma in 4 of Eggel's cases, of alcoholism in 30, gallstones in 14 and lues in 4. Trauma was apparently a direct factor in 7 cases.

The relation of cirrhosis to carcinoma of the liver is debatable. Some degree of cirrhosis was present in 85.4 per cent. of Eggel's series. There were, however, in the 163 reported cases but 69 which showed well-developed cirrhosis, nearly all of which were of the atrophic type. In these 69 cases there was a history of alcoholism in 30 only and of lues in 2. With our present knowledge of the origin of primary carcinoma in solid viscera it can be stated only that cirrhosis and carcinoma may coexist without causal relation in most cases; cirrhosis may precede or follow the growth, each process developing independently, or the same process that produces the one may cause the other.

Peabody⁵ observes that the increase in connective tissue in secondary hepatic carcinomas "is limited to the proximity of the new growth."

SYMPTOMS

The growth may run its course without a single symptom before death, which may be due to a fatal hemorrhage, as in Ewing's case,³ or to some intercurrent disease. This, however, is exceptional. As a rule, there is disturbance of digestion as the first and almost constant symptom. The clinical histories in 147 of Eggel's cases showed the presence of icterus in 61 per cent., ascites in 58.5 per cent., edema of extremities in 41 per cent., enlarged spleen in 32 per cent., and fever in 14 per cent. Anemia, emaciation and cachexia come on apace. The duration from the appearance of the first symptoms is three or four weeks to two and a half years. In the latter the early symptoms are doubtless due to the cirrhosis, which may argue for this being a precursor of the cancer in certain cases. The average duration after development of the cancer proper is about six months.

DIAGNOSIS

"Diagnosis is difficult and experience fallacious." The symptoms above noted are common to a number of conditions, and the physical signs may lead us astray. Our examination should, therefore, include especially the uterus and adnexa, rectum and colon, as most probable sites of the primary growth. Atrophic cirrhosis may obscure a primary carcinoma, unless it be massive, the liver to physical examination being actually smaller than normal.

PAINLESS AND PAINFUL ANGINA PECTORIS *

WILLIAM WATT KERR, M.D.

Professor of Clinical Medicine in the University of California
SAN FRANCISCO

Eleven years ago I presented¹ a paper to the California Academy of Medicine entitled "Cases of Angina Sine Dolore, Due to Disease of the Right Ventricle." The matter gave rise to some discussion at the time but dropped out of sight until within the last few months when Dr. Jellinek and Dr. Cooper advanced the same idea without being aware of the existence of my earlier contribution. It is possible that further investigation may be encouraged by a report of some of the cases that suggested such a hypothesis, together with conclusions reached from personal observation.

Confusion may be avoided by making the preliminary statement that while all the cases mentioned in this paper are examples of angina sine dolore associated with disease of the right ventricle I must not be understood as asserting that the painless variety is the only form of angina associated with disease of the right heart. Furthermore it is suggested that the painless angina attack is the sudden and temporary failure of a weak or diseased right ventricle, which, for the time, is unable to maintain the pulmonary circulation; while painful angina is due to the sudden obstruction of some part of the coronary circulation, either organic or spasmodic in character. I have suggested that cardiac asthma is an indication of disease of the right ventricle but I do not say that it is limited to cases in which the right ventricle alone is affected; on the contrary it is very frequently found in cases in which both ventricles are involved, as in patients in the last stages of mitral incompetence after failure of compensation has taken place; but the presence of the symptom under such circumstances signifies that the right ventricle is seriously diseased as well as the left.

As the phenomenon of cardiac asthma in relation to diseases of the right ventricle will be more easily studied where it was the only symptom present, the following cases with the reports of the autopsies are presented for consideration.

CASE 1.—A mechanic, aged 24, rather under the average weight, of good habits, complained of pain about the precordia. The family physician failed to find any sign of heart disease and attributed the discomfort to strain caused by playing on the cornet. He therefore forbade the use of the instrument, and prescribed a tonic treatment, under which he improved for several months; but the distress recurred, and on one occasion he had an attack which his friends said was "something like a fainting fit," but he asked for fresh air and appeared to be perfectly conscious. When I saw him soon afterward he appeared to be in his usual health. About thirty-six hours later, while eating supper, he experienced another seizure, which he at once realized to be fatal, and in little more than thirty minutes he died, after showing signs of gradually increasing heart failure. I was not present at the autopsy, but the family physician told me that there was marked fatty degeneration of the right ventricle.

CASE 2.—A lawyer, aged 40, was suffering from intermittent fever which had lasted for several months, and also from an acute orchitis. It was nearly five weeks before he was well enough to be pronounced convalescent. In the hope that it would hasten his recovery, he decided to take a trip east, but, before leaving, he called at my office and asked me to examine his heart, as he had a feeling of oppression over his chest and a constant desire to take a long inspiration. Careful examination of the pulse and chest failed to reveal any signs

of disease, and the patient was dismissed with the assurance that it was simply a temporary weakness resulting from his long illness. Next morning I was surprised to learn that he had been found dead in bed. The coroner's autopsy showed the left ventricle to be healthy in every respect; but through the entire thickness of the wall of the right ventricle there was a band of fat nearly one inch in width, and in the cavity of the ventricle there were two white clots, one lozenge-shaped, measuring about one by one and a half inches, and a second, about seven inches long and as thick as a lead pencil, extending from the ventricle into the pulmonary artery. Evidently the streak of fat in the ventricular wall had prevented a complete systole, so that the ventricle never was perfectly emptied, and the clots were permitted to form during his prolonged rest in the recumbent position.

CASE 3.—A merchant, aged 63, suffered with precordial anxiety and slight attacks of dyspnea. The pulse was good and the area of cardiac dulness normal, but there was a slight musical intonation of the second sound in the aortic area, so that instead of the usual "lubb tup," we heard "lubb toomp." There was also slight edema of the feet. The autopsy showed that the left ventricle was healthy, but that there was considerable fatty degeneration of the right ventricle and atheroma at the base of the aorta.

CASE 4.—Another case very similar to the preceding was seen on several occasions in consultation with Dr. Henry Gibbons. The patient was an elderly man and was subject to attacks of cardiac asthma that would come on without any special cause; some occurred in the evening on different occasions when he was quietly seated with the family and others woke him up during the night. The radial pulse was small and quick during the attacks but so surprisingly good between them that we searched for some explanation beyond the cardiac condition. The patient died during a seizure and autopsy showed a degenerated right ventricle.

CASE 5.—A physician, who was present when my original paper was presented to the academy, on many subsequent occasions remarked that he was suffering from painless angina, but as examination failed to reveal any valvular trouble or signs of circulatory weakness, and as the attacks were very transient, much of his distress was attributed to his highly emotional temperament. It was, therefore, with considerable shock that I learned of his sudden death about 3 o'clock in the morning nearly three years later. An autopsy showed atheroma at the root of the aorta, the cardiac muscle in apparently good condition for a man of his years, but the right heart dilated so as to press on the vena azygos and produce a moderate degree of hydrothorax on the right side.

Other cases of cardiac asthma in which autopsy revealed disease of the right ventricle could be reported, but enough have been mentioned to illustrate the frequency with which angina sine dolore and diseased right heart are associated.

The type of breathlessness met under such circumstances is altogether different from ordinary cardiac dyspnea; it is a suffocative paroxysm that may follow exertion or emotion but just as frequently may occur without any evident cause. It does not present the same signs as spasmodic bronchial asthma, as the air enters the lungs freely and there is no indication of obstruction in the bronchi except in those cases in which complete cardiac failure is associated with sudden edema of the lungs or in which the paroxysm comes on as an occasional feature in patients in whom compensation has failed and pulmonary changes have already existed. The attack is simply a paroxysm of air hunger which the patient tries to satisfy by quick and deep inspirations. Instead of the quick forcible inspiration with prolonged expiration that is characteristic of bronchial asthma we have a forcible inspiration with a quick and frequently a gasping expiration. It has not been my experience to find any increase in the ten-

* Read before the San Joaquin County Medical Society, Feb. 26, 1909.
1. Occidental Medical Times, May 1898.

sion of the pulse during these attacks of painless angina; on the contrary it is a rapid pulse, small and of diminished force, but it is frequently a matter of surprise to observe how quickly the pulse will recover after the paroxysm has passed.

In these cases three features were noticed particularly: 1. There were changes in the wall of the right ventricle. 2. During the attack the pulse was small and feeble. 3. After the attack was over and between the various seizures the radial pulse was of good quality. With these facts, the following explanation of the seizure is possible.

The condition to start with is a right ventricle in a state of malnutrition as a result either of defective coronary circulation or of impaired metabolism. Such a muscle has very little reserve force and its assimilative powers are diminished so that it is easily exhausted either by a demand for sudden effort or by any interference with its blood supply. The conditions under which cardiac asthma is most frequently observed, apart from sudden effort to which the heart is unable to respond, are when the patient is resting after mental or physical fatigue, also during the early hours of sleep, and occasionally after a heavy meal or one that is slow of digestion, especially if the patient goes to sleep before digestion is completed. The improved methods for observing blood pressure that have been devised during the last few years show that these are exactly the conditions under which lowering of the aortic and consequently of the coronary blood pressure is sure to be found. All observers are agreed that exertion of any kind at first induces a rise in pressure, but that if prolonged it may ultimately be accompanied and invariably is followed by a fall. Also during the first hours of sleep the pressure is very low and rises gradually toward the time of waking. The results of observations during digestion are somewhat conflicting and possibly depend to some extent on the character of the food and the assimilative powers of the patient. The majority of investigators, however, report a fall during digestion and attribute it to dilatation of the splanchnic area.

Physiologists tell us that muscle fatigue is simply due to the accumulation of the products of activity in the muscle acting as poisons on its protoplasm, and that we must depend on the activity of the circulation for their removal and the reconstruction of the tissues. If, therefore, the coronary circulation becomes depressed in a cardiac muscle that is already deficient in reserve force and recuperative power it need not occasion surprise if at times the muscular contractions are not sufficiently strong to discharge their physiologic function and that corresponding symptoms should manifest themselves. It is important that this should be recognized in regard to treatment because the injudicious use of vasodilators, such as nitroglycerin, will still farther reduce the aortic pressure and aggravate the condition.

If the disease be limited to the right ventricle we can easily understand how the radial pulse improves so rapidly when the seizure is over, but in cases in which the asthma is simply intercurrent on the symptoms of general cardiac disturbance such as failure of compensation in long-standing cases of mitral incompetence such improvement is not found and should not be expected.

It is impossible to explain the absence of angina sine dolore in some cases of dilated or fatty heart, unless it be that sufficient healthy muscular fibers remain to

produce a complete systole, or that the exciting causes, such as emotional disturbance and physical or mental strain, have not been out of proportion to the capabilities of the heart. That extensive degeneration may exist without producing any symptoms to awaken suspicions of heart disease is a well-established fact; indeed, we frequently hear that some man, who never was supposed to be the victim of cardiac disturbance, has died suddenly after some strain or excitement, and that autopsy has shown degeneration of the heart muscle. In a number of such cases inquiry will ascertain that death was ushered in by an attack of the peculiar form of dyspnea that has been described as angina sine dolore.

Painless angina is much more common than one would suppose it to be from the infrequency with which it is mentioned; but, in all probability, the disease is not always recognized, and the patient's sufferings are attributed to hysteria or some reflex disturbance. When the symptoms are accompanied by a dilated right heart or distinctly atheromatous changes the diagnosis is easy, but when physical signs are absent it is difficult to arrive at an absolute opinion. If, when free from the paroxysms, the patient continually suffers from a feeling of weight or distress over the precordia, and has a tendency to take occasional deep inspirations, there is a strong probability that the right ventricle is affected: and this amounts to certainty if the symptoms are invariably produced or aggravated by exertion.

This form of angina is entirely different from the painful variety and in many instances demands a diametrically opposite treatment. The cause of angina pectoris is still a matter for discussion, but in all probability it is due to some local obstruction in the coronary circulation which may be organic, spasmodic, or a combination of both. The fact that the radial pulse varies in different cases, the pressure being sometimes high and at other times low, indicates that the attacks can not invariably be attributed to increased resistance in the peripheral circulation. It has been suggested that angina pectoris is due to strain on the heart by obstruction in the arterial system and that while in certain cases the vascular pressure may be actually low, nevertheless it may be too high for the capabilities of the myocardium. I have seen a very large number of patients with weak and dilated hearts who under varying conditions were subjected to considerable increase in peripheral resistance and suffered precordial pain and distress in consequence, but the proportion of those in whom a typical angina attack ensued was infinitesimal. Such an experience leads to the conclusion that the explanation of the symptoms characteristic of angina pectoris must be sought elsewhere than in the condition of the cardiac muscle.

One can hardly witness an attack of angina without thinking of the extreme pain that is produced in other parts of the body as a result of sudden anemia following embolism, vasomotor spasm or some other cause, and this, together with the fact that postmortem examination so frequently shows disease of the coronary arteries, either in their main trunks or in their smaller muscular branches, forcibly suggests the idea that this malady may be due to ischemia from some form of obstruction in the coronary circulation, and that the myocardial changes can be attributed to the same arterial disturbance, the muscular degeneration being an associated lesion but having no causal relation to the

intensely painful seizures. The causes of the obstruction are not the same in every case. It may be that the lumen of the arteriole is narrowed from disease so that under exertion some part of the heart muscle does not obtain a sufficient supply of blood and therefore an ischemia is established; or we may have a rise in blood pressure during which the coronaries participate in the general arterial contraction, but this contraction may be sufficient to obliterate the stream in one of the cardiac branches which is already narrowed by disease. It is perfectly possible that some of the attacks are due to very minute emboli or sclerosis permanently obliterating a small vessel. The rapidity with which in many instances an attack yields to vasodilators such as nitroglycerin or amyl nitrite has for many years warranted the belief that vascular spasm plays a very prominent part in the production of the pain, but the fact that general high blood pressure is present in some cases of angina pectoris, absent in others, and present in a very large number of people who never suffer from angina pectoris inclines me to the belief that spasm of the coronary arteries is the essential feature in producing the attack and that the relief that follows the administration of such substances as nitroglycerin is due to the relaxation of the coronary spasm which would take place independently of any fall in general blood pressure; in short, that in those cases in which the blood pressure is high the pain is due to overcontraction of some coronary branch and not to pressure exerted on the ventricular cavity on account of increased peripheral resistance. Such a hypothesis explains the existence of angina irrespective of high or low blood pressure; it explains those cases, sometimes described as spurious angina, in which patients have suffered from a typical seizure consequent on errors in digestion and metabolism; it explains the improvement in those patients who at one time could not walk across a room without provoking a seizure but who as a result of appropriate treatment are able to walk two or three miles without difficulty.

This local vasomotor spasm is nothing new in medicine. In Raynaud's disease we can observe it in the finger, on the body surface, or on some part where it may persist with such intensity as to terminate in multiple gangrene or pass away and leave the patient with very little evidence of the attack. Transient loss of consciousness and brief hemiplegias in the course of the disease indicate that not even the cerebral vessels are exempt from the spasmodic contraction. It is therefore perfectly possible that similar local spasm may affect the vessels of the heart.

It seems, therefore, that with our present knowledge we are warranted in believing that angina pectoris is due to some form of obstruction in the coronary circulation; that the changes in the peripheral blood pressure are coincidences rather than causes of the attack; and that the degeneration of the cardiac muscle may be the consequence of the impaired coronary supply but not the cause of the painful seizure.

The treatment of those two forms of angina will be entirely different during the seizures, but as a rule it is identical between the paroxysms. Since cardiac asthma is due to failure of the right ventricle rapidly acting stimulants, such as caffeine, camphor, or strophanthus, will be indicated for the relief of the paroxysm; while angina pectoris, on account of the coronary spasm, will call for vasodilators such as nitrite of amyl, nitroglycerin or morphin. It not infrequently

happens that the subject of coronary spasm is also suffering from a weak heart and under such circumstances a combination of heart stimulant and antispasmodic is demanded.

Between the attacks the treatment is that which has been recommended in cases of chronic myocarditis and arteriosclerosis. The regulation of diet, in regard to both variety and quantity, so that the circulation never will be overloaded with food or waste material, is of the greatest importance. Avoidance of mental and physical strain and the regulation of exercise in accordance with the capabilities of each individual case must be carefully observed. The administration of arsenic and the prolonged use of iodids in small doses for a period of several months will be found in many instances to have a very beneficial effect on both the cardiac muscle and the blood vessels. And last, we never should neglect the judicious use of remedies which will aid in eliminating by their natural channels all toxic substances resulting from physiologic activity or food metabolism.

2605 California Street.

A NEW METHOD FOR THE TRANSFUSION OF BLOOD

AN EXPERIMENTAL STUDY *

ROBERT T. FRANK, A.M., M.D.

AND

GEORGE BAEHR, M.D.

NEW YORK

A method of transfusion by means of a vascular bridge, composed of a fresh animal blood vessel, interposed between the artery of the donor and the vein of the recipient, was described in a preliminary communication¹ some months ago. Since then further experiments have been carried out in order to find means of preserving ready for use the vascular bridge, which, for the sake of brevity, will be called simply the "link" throughout the rest of the paper.

It is not our purpose to discuss when and where transfusion is indicated. The future alone can show whether the present enthusiasm is justified, and whether transfusion is here to stay. That, however, direct transfusion is being quite largely practiced is readily seen by the numerous modifications of the technic constantly appearing in the literature, and by a recent discussion held at the meeting of the New York Academy of Medicine, Surgical Section, Jan. 8, 1909. Dr. Hartwell, in connection with a paper he then read² on a new method of transfusion by means of direct intubation of the artery into the vein, referred to forty-one cases of transfusion done with the aid of various cannulae (chiefly by Crile's technic) which he had collected through private communication with eighteen surgeons of New York City. In this series twenty technical failures were recorded. It has been our privilege to witness personally twelve transfusions on the human subject. In all of these the exposure of the artery proved tedious and in some cases difficult, chiefly because of numerous minute side branches which required ligation. If these branches are seen before they are cut

across, ligation is not difficult; if on the other hand, as not infrequently happens, they are torn, annoying bleeding occurs, to stop which it may be necessary to apply lateral ligatures on the artery, thus partly occluding its lumen, either through actual constriction or through the resulting parietal thrombus. Another difficulty is encountered in the choice of the cannula; if it is too small the vessel is constricted, if too large cuffing will prove difficult or impossible. This difficulty is to some extent prevented by the use of either the Elsberg³ or Levin⁴ instrument. Again when the final union of artery and vein is undertaken, the operator is obliged to work in a cramped space at great disadvantage. In consequence of these difficulties it requires from twenty to forty-five minutes to establish union between artery and vein, if everything goes smoothly, while double that length of time is not unusual. Such prolonged exposures necessarily produces contraction of the radial artery with consequent im-

ately a considerable diminution in caliber was caused by the contraction due to the elastic tunic, which served to shorten and at the same time thicken the vessel wall, thus producing a constriction of greater or lesser degree within the cannula. All these faults are overcome by means of the following method of preparation.

2. *Formalinized Links*.—Fresh carotids are obtained from medium-sized dogs, immediately after death, carefully washed out with cold normal salt solution, and stripped of any surrounding connective tissue. The adventitia at both ends is drawn over the cut end of the artery and snipped off. A Crile, or other tube of appropriate size, is selected, the artery pushed through the tube and by means of two eye forceps cuffed and secured with a fine silk ligature tied in the groove nearest to the handle. The opposite vessel end is similarly cuffed over another Crile tube, care being taken to have the handles pointing approximately in the same direction transverse to the long axis of the link in order to avoid torsion subsequently. The completed link is now stretched and kept stretched by means of a

Fig. 1.—Wire frame used to stretch the link during preservation, with cannulae in position.

Fig. 2.—Crile cannula slightly modified in shape. The end is more pointed and the grooves for ligatures are farther removed from the opening. This favors easier introduction.

Fig. 3.—Link ready for use, in sealed test-tube, immersed in paraffin oil.

pairment of the flow of blood, and greatly favors clotting, especially if all the safeguards so necessary in vascular surgery are not scrupulously observed.

ADVANTAGES OF THE LINK

The use of the link offers the following advantages:

1. A sufficient length of vessel is obtained without extensive dissection of the artery of the donor or the vein of the recipient.
2. The link as now prepared by us has lost some of its elasticity and is well stretched, so as to afford an unobstructed lumen within the cannulae.
3. The technic is familiar to every surgeon from its similarity to that used in intravenous infusion.

FORMS OF LINKS

1. *Fresh Links*.—The fresh links, as first suggested, required preparation immediately before they were needed, which entailed obtaining a dog of suitable size, aseptic removal of its two carotids, etc. It was also found that unless the carotid fitted the cannula accu-

Fig. 4.—Schema of transfusion.

small frame readily improvised of soft brass wire (Fig. 1) which serves to keep the cannula sufficiently far apart to thin the walls of the link and thus afford a wide lumen within the cannula. The tension should not be so excessive as to flatten the link at its central portion.

All the steps just enumerated may be taken without aseptic precautions. The link, stretched on its wire frame, is now placed in a wide test-tube, containing freshly prepared formalin of 2 per cent. strength (2 c.c. of chemically pure formalin of 40 per cent., in 98 c.c. of water) and well stoppered with a thick cotton plug. After twenty-four hours, using the usual bacteriologic technic, to avoid contamination, the link is transferred into a tube of sterile normal salt solution and after one-half to one hour transferred to a similar tube for the same period. These two changes serves to remove any excess of formalin, which if left, in time renders the links brittle and useless. Finally, the link is preserved for future use in sterile paraffin oil, the end of the test-tube being sealed with a blow-pipe flame (Fig. 3). The method of preservation serves to impair the resiliency of the link sufficiently to keep the lumen well open and to increase the distance between the cannula permanently, even after the wire frame is

4. Levin: *New York Med. Jour.*, Oct. 3, 1908.

removed. The optimum time in formalin has been found to be twenty-four hours, but fairly effective links were obtained up to forty-eight hours. Links used direct from the formalin, or from the salt solution produces no clotting, showing that the paraffin oil is not essential. This fluid was chosen because it helps to soften the tissues, is bland, and later proves useful at the transfusion. Links kept by this method for ninety days were pliable and as elastic as thin rubber tubing.⁵

3. *Dried Links*.—We have lately tried another method of preserving the links, suggested by Dr. Carrel.⁶ As applied to our work the steps enumerated in obtaining and preparing the links are the same as those previously described up to that of the placing them in the formalin solution, except that the fresh link should not be as tightly stretched. Instead of being placed in

the cannula, as is the case with freshly obtained vessels. 4. *Glass Tubes*.—Before describing the application of the links, it may prove of interest to mention that during the course of the experiments we attempted to use glass tubes, carefully coated inside and out with hard paraffin. In only one instance out of five did clotting fail to occur within twelve to seventeen minutes. Dr. Alexis Carrel, in a private communication, informed us that he also found glass tubes unreliable for the same reason.

The appended summary of experiments shows that of twenty-six transfusions performed with prepared links, but one failed. In this instance (experiment 15) the link had been kinked during preparation and therefore did not permit the blood to pass through at all.⁷ It is now our custom to test the permeability of the link before using, by means of a small syringe filled with salt

formalin the link is dried for twenty-four to forty-eight hours over fresh anhydrous calcium chlorid in the ordinary chemical drying chamber. By this time it looks dry, shriveled and brittle as parchment. It is now placed in a sterile test-tube and heated for twelve to fifteen minutes at 100 to 105 C in the dry sterilizer. The tube is then sealed. About an hour and a half before the dried link is to be used it is placed in sterile salt solution or Lock's fluid. At the expiration of that time it will have regained its normal appearance and elasticity. This method has proved excellent and has but one drawback, namely, that the great elasticity of the vessel serves partially to occlude the lumen inside

solution, in order to assure ourselves that the lumen is unobstructed and in order to wash out the paraffin oil. To favor clotting, the blood current was repeatedly interrupted. In two experiments, links inserted in the carotid artery were tied off and the blood allowed to remain within the lumen of the link for fifteen and thirty minutes without resulting thrombus formation.

TECHNIC OF TRANSFUSION BY THE USE OF VASCULAR LINKS

About one inch of the artery of the donor, in man the radial, is exposed under local infiltration anesthesia without the use of adrenalin), no great care being exercised in freeing the vessel from its sheath. Two

5. It has been found necessary to have both the cannulae of the wire frame gold-plated (silver-plated might do as well), as an electrolytic reaction is set up, if two different metals are used, which causes a deposit of copper on the surface of the link, thus favoring clotting.

6. Carrel: Proc. Phil. Soc. Philadelphia, Nov. 6, 1908.

7. An attempt to sterilize a link in the Arnold sterilizer proved a failure. In one experiment in which the link was kept for nineteen days in 4 per cent. formalin and used direct from this, clotting occurred.

ligatures are passed around the artery, the distal one being applied as far peripheral as possible and tied, the proximal left loose. A vein of fair size in the recipient is similarly exposed (in infants the femoral must be used), and the ligatures passed, the distal one again being tied. On both artery and vein a *serre-fine* is applied proximal to the loose ligature in order to stop the circulation temporarily.

The link is emptied of the paraffin oil and placed in salt solution to be ready for use. The artery is pulled out of the wound by means of the ligature and with a snip of the scissors a small transverse slit is made into its lumen. The edges of the slit are grasped on either side with two fine eye forceps and drawn apart. Through this aperture the one end of the cuffed link is introduced toward the heart (the handle of the cannula being steadied with an artery forceps) and the loose ligature tied in the first groove of the cannula. The vein is treated similarly, the opposite end of the link being inserted toward the heart, and the ligature tied. (It is well to make the slit in the vein near the distal angle of the skin wound in order to have a portion of the vein visible and palpable, as this enables the operator to see and feel the pulsation and thus control the transfusion, or at once to recognize a stoppage of the flow.) The *serre-fines* are now removed, the one on the vein first, and the exchange of blood allowed to proceed (Fig. 4). Throughout the manipulation both wounds should be kept well moistened with salt solution. During the transfusion the link should be supported by a gauze sponge saturated in salt solution and covered by another moist compress.

When enough blood has been obtained both artery and vein are tied off, the small injured part of the vessels being excised. The skin wound is then closed.

This technic closely resembles that so familiar in intravenous saline infusion, the infusion cannula being represented by the cuffed link. Should the opening in the artery prove too small, a very fine blunt artery forceps or scissors may be inserted closed, and then opened in order to stretch the lumen.

For adults, carotids obtained from medium-sized dogs should prove the proper size, as they are easily cuffed on the large or medium Crile tube. If a smaller cannula is desired, a cat's carotid is available, though of course much shorter in length. The stretched dog's vessel is three and one-half to four inches in length, the cat's half that. The hypothesis that clotting is due to an alien blood vessel has been disproved by the work of numerous investigators. We also have used rabbits' and cats' vessels on dogs with complete success.

TESTS OF THE STERILITY OF PREPARED LINKS

A series of links were prepared, without aseptic precautions and immersed for two to eight hours in 2 per cent. and 4 per cent. formalin. This entire series proved sterile. A similar series of links were infected with the spore-bearing *Bacillus anthracoides*, incubated for forty-eight hours, immersed for one to thirty-six hours in 2 per cent. formalin and then tested after thorough removal of the formalin. No growth took place in the tubes subjected to formalin for more than ten hours. Numerous control experiments showed abundant growth.

SUMMARY

1. The links are prepared by cuffing dog's carotids at both ends over Crile's tubes, stretching them on a wire frame and fixing them for twenty-four hours in

2 per cent formalin. The formalin is removed by two changes of sterile salt solution (thirty to sixty minutes each), and the links permanently preserved in sterile paraffin oil.

2. Of twenty-six transfusions performed by means of prepared links, but one failed (owing to kinking of the vessel during its preservation).

3. The method of preservation kills bacteria, including spore-bearers.

4. The technic if transfusion corresponds closely to that used in intravenous saline infusions.

As far as can be predicted, the use of the prepared links affords a simpler and easier method than those hitherto described, and it is hoped that it will soon receive trial on the human subject.⁸

In conclusion we desire to express our obligations to Dr. T. Mitchell Prudden for extending to us the courtesies of the laboratory, to Dr. Carrel for his kindness in permitting us to use his method of preparing vessels before he had published it, to Dr. H. Zinzer for supplying us with test cultures, and to Dr. Simons for assistance in the bacteriologic tests.

THE INCUNABULA IN THE SENN COLLECTION AT THE JOHN CRERAR LIBRARY*

AKSEL G. S. JOSEPHSON

Cataloguer, the John Crerar Library
CHICAGO

The most interesting part of the Senn collection is undoubtedly the library of Professor Wilhelm Baum, of Göttingen, which Dr. Senn purchased at auction in 1885. Professor Baum was one of the most learned surgeons of his time and exercised a wide influence on succeeding generations of students and physicians, both as a teacher and practical surgeon, although he wrote practically nothing after receiving his degree in 1822. From 1829 to 1842 he was the head of the city hospital in Dantzig, and from 1842 to 1875 held positions as professor of surgery, first at Greifswald, afterward at Göttingen. After his retirement in 1875 he spent his leisure in collecting material for a history of surgery, though he never came so far as to write any part of it. Dr. Baum was a book collector all his life, and he placed his library most generously at the disposal of other students; it is a working scholar's library, not a bibliophile's; there are no tall copies in it, no books printed

8. Through the kindness of Dr. A. V. Moschcowitz we have recently had the opportunity of performing a transfusion on a human being by our method. Technically the operation was as simple as when performed on animals. The blood ran freely for six minutes and then ceased to flow. During this short time the hemoglobin rose from below 10 per cent. on the Sahli scale to 20 per cent.; next day it was found to be 27 per cent.

From this single trial we have learned that the method proposed is as devoid of danger as other methods. We have found that a cannula corresponding to the outside diameter of the radial artery is readily introduced into this elastic vessel, and that the link may be advantageously reduced to a length of two or two and a half inches.

The stoppage of the flow was due to a small clot at the venous end of the link, within the vein; for when the cannula was withdrawn from the vein, the blood spurted freely through the link. The only partial success of the trial was, in our opinion, due to the deposit of a copper salt on the surface of the link. This may be avoided (as mentioned in Note 5) by using cannulae and wire frame both gold-plated.

* Read at a regular meeting of the staff of the John Crerar Library, March 24, 1909; also at the annual meeting of the Chicago Chapter of the Bibliographical Society of America, April 29, 1909. The historical data in this paper have been taken chiefly from Puschmann's "Handbuch der Geschichte der Medizin," Gurli's "Geschichte der Chirurgie," and Sudhoff's "Tradition und Naturbeachtung in den Illustrationen medizinischer Handschriften und Frühdrucke."

on vellum, comparatively few remarkable for rarity. The auction catalogue contains over 3,000 numbers, of which 891 come under the head of surgery, 434 under pathology, 270 under anatomy, physiology, etc., 122 under history and bibliography. Early medical and surgical writers are very largely represented, both in early and modern editions; the catalogue contains under this head about 600 numbers, and 15 or 16 of these were printed in the fifteenth century.

The object of the earliest printers was to reproduce manuscripts. If we keep this in mind, we shall better understand two peculiarities in which the incunabula and other early printed books differ from those of more modern times. It had not been the custom of the scribes to use a whole sheet of paper or vellum for a title-page; the material was much too expensive for such waste; and they were not in the habit of signing their names at the end of the manuscripts. The development of the title-page in the early printed books is an interesting chapter, but it would carry us too far to go into that subject now; as to the adding of the printer's name at the end of the book, in the colophon, I only wish to call attention to the fact that, while the scribe did not put his name at the end of the manuscript, the rubricator did, and the first book that contains in the colophon the name of its printer, the celebrated 1457 *Psalterium*, is particularly remarkable for its beautiful illuminated initials which were not painted by hand, but printed in colors from type, and to this fact the printers, Johann Fust and Peter Schöffer, call particular attention in the colophon.

The oldest book in Dr. Baum's library was printed in 1487, in Venice, by Baptista de Tortis. It has no title-page, nor is there anywhere in the book an indication of what its title might be: the first page is blank, the second contains the table of contents, which fills the whole page. The third page begins: "Incipit isagoge Joannitii ad tegni Galieni." i. e., "Here begins Johannitus' introduction to Galen's *Microtechnē*," which latter is the first work contained in the volume. As a matter of fact, the volume is a collection of medical treatises, translated from the Greek into Arabic by the above-mentioned Johannitus, or Hunain ibn Ishāk, and from Arabic into Latin by Gherardo of Cremona. Other editions of the collection give it the title "*Articella*." Hunain ibn Ishāk was the most famous of those Arabic translators who did so much to preserve Greek literature during the middle ages. He was born in the year 809 and studied under the celebrated Mesuē in Bagdad, in which city he, after having spent some years in travel, settled as physician to the khalif; the latter encouraged him particularly in his translating the works of Greek medical writers into Arabic.

Bound with "*Articella*" is a copy of Avicenna's "*De anima*," the only edition of this work that was printed alone in the fifteenth century; the date of printing is not given, but it is probable that it was printed about the same time as the "*Articella*"; the printer was Antonio Carcano of Pavia. The two books are bound together in wooden boards covered by pressed leather with metal corners and clasps, though the main parts of the clasps have been broken off. On the outside of the front cover is a piece of vellum pasted on to it, with the inscription in medieval hand: "*Articella Avicenna de anima*."

An editio princeps of interest is the 1492 edition of John of Gadde's "*Rosa Anglica*," printed also in

Pavia, by Leonardo Gerla, for Giovanni Antonio Birreta, whose mark we find on the last page. It was the 1502 edition of this book that, on account of its somewhat peculiar, though perfectly correct imprint date, caused some bibliographers and librarians to record an edition of 1516, as Mr. B. A. Finney has told.¹ The author of this book is mentioned in Chaucer's "*Canterbury Tales*," and it has been suggested, it would seem with good reason, that he was the model for the "*doctor of phisicke*" of whom Chaucer says that "in all this world ne was ther none him like"; he was certainly one of the best known medical men of his time, and his book supplies much information as to medical practice and custom during the fourteenth century.

A book that is of interest on account of its publisher, as well as the author of the first work printed in it, is a collection of surgical treatises, beginning with Guy de Chauliac's "*Chirurgia magna*," or, as the author himself called it, "*Collectorium artis chirurgicæ medicinalis*." Guy de Chauliac was, from the year 1342 to his death, some time in the decade beginning 1360, physician to the popes in Avignon and a friend of Petrarch, though the latter otherwise was not favorably inclined toward the medical profession, and particularly not friendly to the physicians attached to the papal court. The "*Collectorium*" is, as its name implies, a compilation, but is of more value than most books of its kind and time, and served as a text-book of surgery as late as in the eighteenth century; the introductory chapter contains a short history of surgery, and we find also in the work an eye-witness' account of the Black Death which ravaged Avignon during his residence there. In this book we have an example of an embryonic title-page which briefly enumerates the titles of the work contained in it. It is printed by Simon of Lovere in Venice, in 1499, for Andrea Torresano, whose daughter Maria this same year married the elder Aldus Manutius; after Aldus' death and during the minority of his sons, Torresano was the manager of the Aldine press. This copy has a beautifully illuminated initial on the first page and a miniature in the margin of the same page.

Giovanni Michele Savonarola, grandfather of Girolamo Savonarola, is the author of two books bound together in pressed pig skin. He was born in Padua, where he received his degree of Doctor of Medicine and later became professor at the university. His "*Practica de ægritudinis*," the book bound first in the volume (the second being his "*Canonica*"), is a general handbook of medicine, based on his observations and experience, and is regarded as one of the best medical works that have come down to us from the middle ages. Both of these books were printed by Bonetus Locatellus for the publisher, Octavianus Scotus.

Two other books were issued by the same printer and publisher—the "*Practica*" of Yuhanna ibn Sarapion, a Syrian, by some called Janus Damascenus, but not to be confused with the elder Mesuē, who is also known by that name; and Pietro di Argellata's "*Chirurgia*," in which the author, who was professor at Bologna, quite frankly acknowledges mistakes in his practice and discusses them as warnings to his students.

Another printing-press in Venice which is represented here is that of the brothers Giovanni and Gregorio di Gregorii, from which several medical works were issued, both during the fifteenth century and the beginning of the sixteenth. Four books under consid-

1. Papers and Proc. Bibliograph. Soc. of America, 1, 71-74. Also Dock, George: Janus, Harlem, 1907, xii, 425-435.

eration were printed by them: Alessandro Benedetti's "Collectiones medicinae," a small pamphlet without place, date or printer and by Mlle. Pellechet ascribed to Aldus, though Robert Proctor has since shown that the book was printed from types that belonged to the Gregorii; Bernard de Gordon's "Lilium medicinae," highly valued for its clearness and conciseness, and which gives a good idea of the standpoint of medicine in the thirteenth century; its author was professor at Montpellier from 1285 and dictated the present work to his students in the year 1305: the book has a wood cut on the title-page to the index, that to the work itself being quite plain.

"Theicrisi," or "Altheisir," is the title of the third book in this group; it has for its author Avenzoar, the latest of the great Arabian physicians.

The fourth book, called "Fasciculum Medicine," is of interest on account of its illustrations, which are the earliest examples of anatomic drawings reproduced in wood cuts, though the present edition, printed in 1500, is not the first (the first edition was printed in 1491); the author of the book, Johannes Ketham, was a German physician, living in Italy, but of whom nothing further is known; it should be said, though, that the illustrations are not original with him; some of them are of interest for the student of the history of costume and furniture.

Mondino da Luzzi's "Anathomia" is one of the three books in the collection that were printed in Germany. It has neither place, date nor name of printer, but it was printed with the same types with which Martin Landsberg printed in Leipsic after 1492, and has, therefore, been assigned to this printer; it was printed before 1500. Mondino was the first anatomist since the time of the Ptolemys to dissect human bodies, and his book was intended as a handbook for anatomic exercises. From 1290 to his death in 1326 he was a teacher at the university of Bologna.

The other two books printed in Germany are bound together; they are not medical in character, though one of them, Bartholomæus Anglicus (or Glanvilla's) encyclopedia, "De proprietatibus rerum," contains a good deal of medical information. It was printed with types used by a printer in Heidelberg whose name is not known, but who is commonly spoken of as "the printer of Lindelbach," after the title of one of his books. The work bound together with this, Werner von Rolewinck's "Fasciculum temporum," was one of the most popular books of its time. Leo Baer, in his work, "Die illustrierten Historienbücher des 15. Jahrhunderts," enumerates not less than thirty-four editions of it printed before the year 1501; the first two editions were printed in the same year, 1474, both in Cologne, but by different printers; the present edition is one of several printed by Johannes Prüss in Strassburg in the decade beginning 1490; but it does not bear his name nor is it dated. The author of this work was a Carthusian friar and inmate of the St. Barbara monastery in Cologne, where he died in 1502, 77 years of age. He was the author of several books, both historical and theological.

One volume still remains to be mentioned, though it is likely that it should not have been classed among the incunabula. It is an anonymous edition of the "Regimen Sanitatis Salernitanum," with Arnoldus de Villanova's commentary, a versified essay on hygiene prepared by the physicians connected with the famous school of Salerno for the benefit of Duke Robert of

Normandy, who in 1096 visited his relative, Duke Rugiero of Salerno, on his way to take part in the first crusade. Hain, Mlle. Pellechet and other bibliographers count this edition among incunabula, but Robert Proctor does not include it in the first part of his "Index to Early Printed Books in the British Museum," but merely refers to it as being "not fifteenth century." For my part, I have not been able to come to any definite conclusion, but have followed the lead of the majority in assigning to it tentatively the date 1500; I may say, however, that I have not been able to identify the type with which it is printed with any of those described in Haebler's "Typenrepertorium der Wiegendrucke"; when the section for Italy of the second part of Proctor's "Index" appears we shall probably be able to determine the date of the book; it is also probable that a closer study of the wood cut on the title-page will help to solve the problem.

STREPTOCOCCIC INFECTIONS OF THE THROAT *

RICHMOND McKINNEY, A.M., M.D.

Professor of the Diseases of the Nose, Throat and Ear, College of Physicians and Surgeons
MEMPHIS

During the past few months a great deal of attention has been attracted to the subject of streptococcic infections of the throat, and there have been two contributions to the literature of the subject which are of more than ordinary interest. At the Chicago meeting of the American Medical Association last June, Dr. Alice G. Bryant, of Boston, read a paper¹ describing a series of cases in which the infection fastened on the so-called adenoid tissue found in the pharynx, and in which there were marked symptoms of infection, with temperature ranging from the neighborhood of 100 to 104 F., and at times a free discharge from the nose of a creamy consistency, masses of adenoid tissue sometimes being found in this discharge. Bacteriologic examination of the discharge in the cases reported by Dr. Bryant showed streptococci in abundance.

By far the most interesting article that I have seen on the subject, however, is that by J. O. Hollick,² Medical Officer to the Midland Counties (England) Idiot Asylum, in which is reported an epidemic of streptococcic or "septic" throats which prevailed in the asylum during April of last year, also a similar epidemic in his private practice. The first outbreak was thought to be due to the Klebs-Loeffler bacillus, but bacteriologic examination showed an absence of diphtheria and diphtheroid bacilli, with a plentiful growth of both streptococci and staphylococci. The epidemic occurred first among the nursing staff, and then spread to a number of the inmates. The general symptoms are summarized by Hollick as follows: malaise and pains in the back and neck were prominent, and violent headache in a few cases; no vomiting or other abdominal symptoms. Evening temperature often rose to 104, morning temperature 100 Fahrenheit. Slight soreness existed on one or both sides of the throat and difficulty in swallowing; the submaxillary and glands adjacent to the angle of the jaw and in the triangles of neck enlarged and tender. One or both tonsils showed creamy

2. Lancet, London, Dec. 19, 1908

white secretion, with angry-looking areola of inflammation extending to the anterior pillar of the fauces, and the uvula was often swollen and intensely edematous. There were no points of follicular exudation on tonsils. Urine febrile, and in some cases slight traces of albumin. The exudation rarely extended beyond the anterior pillars of the fauces to the front, or beyond the posterior pillars behind, but much mucopurulent secretion was observed to exude from the lymphoid follicles over the vault of the pharynx, and signs of nasal obstruction pointing to a general engorgement of the lymphoid tissue around the posterior nares and extending through the nares anteriorly were often evident. The exudate in no case extended over the soft palate or uvula. In from two to four days, according to the severity of the infection, the symptoms and local signs decreased, glandular swelling and tenderness remaining for some days or weeks after clearing up of the other symptoms. A tendency to relapse was shown in several cases after subsidence of the temperature.

No sooner had this epidemic abated than one of a similar but severer character occurred in Hollick's practice at a private preparatory school in the same neighborhood. There was a history, before the beginning of the epidemic, of one boy returning to school who had had a sore throat which had imperfectly cleared up. In two or three weeks later a boy was seized with convulsions, and when Hollick saw him after the abatement of the seizure, his temperature was 103 F.; he complained of no sore throat, but his cervical glands were enlarged and tender. When seen next day he had a creamy secretion over both tonsils, but not extending onto the palate, uvula, or faucial pillars. There was much angry congestion over the latter, and he now complained of much difficulty and pain on swallowing. Four other boys on this day were put to bed with rise of temperature, tenderness over the cervical glands, headache, malaise, and some pain on one or both sides on swallowing. One of these showed much cervical glandular enlargement and had a more suspicious look about his fauces and tonsils than the rest. A swab from his throat showed Klebs-Loeffler bacilli. He was treated with 4,000 units of antitoxin. It proved to be a severe case of diphtheria of the fauces and nares, with marked heart and kidney trouble, and the patient succumbed fourteen days after onset of symptoms of cardiac failure.

Swabs from other throats showed Hoffman's diplococci and streptococci but no diphtheria bacilli. Boys fell down like ninepins, says Hollick; in all thirty cases developed, but only in one other of these was the specific bacillus found, this case proving, however, to be very mild.

Hollick calls attention to the well-understood possibility of a "diphtheritic" supervening on or accompanying a "diphtheroid" infection, or of a streptococcal infection going hand and hand with both and gaining sometimes the upper hand.

My reason for quoting so freely from Hollick's article is that he very accurately describes a condition which has prevailed during the past winter to no little extent in Memphis, and also in the surrounding country, and because his experience has been similar to a recent one of mine.

Recently I have had a number of cases of mixed streptococcal infection of the throat to deal with, and the severity of the symptoms in these cases has at times

corresponded with some of the cases reported by Hollick. I shall here report more or less in detail some of the cases that have come under my observation.

CASE 1.—History.—Lavina M., aged 7, seen through the courtesy of Dr. J. A. Crisler, of this city, was brought to my office on November 1, 1908, with a history of having had a severe headache and fever about a week before, since which time her nose had been stopped up and she was unable to breathe through it at all, especially at night. She had been complaining of sore throat for several days, and the mother stated that while she had no thermometer, she was convinced that the child had been having fever. In the meantime, distressing to relate, the child had been going to school.

Examination.—This revealed a confluent pseudomembrane on both faucial tonsils, and extending back onto the pharynx, involving the lateral pillars. Both nares also were filled with this pseudomembrane. There was considerable glandular enlargement on each side of the neck. There was no elevation of temperature (axilla). On removal of portions of the pseudomembrane from the tonsils and pharynx a bleeding surface was left. Swabs and pieces of membrane were immediately taken from the throat and also from the nose, and culture tubes inoculated. Repeated examinations made from these tubes revealed no diphtheria bacilli, but streptococci were found in abundance associated with staphylococci.

I did not see the child again, but heard later that she was entirely well.

As an infection-carrier this patient certainly was a good example, and the anomalous condition of a pseudomembrane, but no diphtheria, was present.

CASE 2.—History.—Charles M., aged 12, was seen by me at his home Dec. 30, 1908. The child had a sore throat and headache, with high fever, for a day or two, accompanied by a purulent discharge from both nares. There was a very disagreeable odor to the nasal discharge, which was detected immediately on entering the room.

Examination.—The boy's throat showed a creamy exudate on either tonsil, without any extension to the soft palate or pharynx. There was a similar creamy discharge from both nares. There was no membrane whatsoever. The submaxillary glands on both sides were considerably enlarged. Temperature at this time was 101.4 F., pulse 102 and very full.

Course of Disease.—The opinion expressed by me to the boy's mother was that the case was very suspicious of faucial and nasal diphtheria, and instructions given to isolate the patient. The next morning at 9 o'clock the temperature was 99, pulse 90, and the child much better. Convalescence was uninterrupted. Cultures made from swabs taken from both nose and throat revealed almost pure streptococci, diphtheria bacilli not being found on repeated examinations.

CASE 3.—Corinne M., aged 5, sister of previous patient, developed a sore throat, running nose and considerable fever January 9.

Examination.—When seen by me on the 10th the faucial tonsils showed some creamy exudate, with no extension, from the tonsils, temperature 102 F., and some enlargement of the submaxillary glands. There was also the same discharge from nares as seen in the previous case, accompanied by the same odor. Swabs were immediately taken from the nose and throat. When the patient was seen next morning the temperature was the same—102 F., pulse 104, and submaxillary glands somewhat more swollen. Bacteriologic examination of spreads from cultures showed a mixed infection of streptococci and staphylococci, the former in great majority, no Klebs-Loeffler bacilli being found in the cultures grown from the swabs taken from either the nose or the throat. On this second morning I suggested antitoxin, but the mother was prejudiced against this agent, saying that she was more afraid of antitoxin than diphtheria, and despite some suspicious symptoms at this time, I did not feel that in the face of this prejudice and the negative bacteriologic report I should urge the use of the serum. Inasmuch as I was very suspicious of the condition of this second child, I repeatedly called for reports from the cultures, but frequent examinations, and these made by several competent physicians, failed to reveal Klebs-Loeffler bacilli.

Course of Disease—The next morning the child's temperature was normal, pulse 102. The following morning the mother telephoned me that the temperature was 102 and in the afternoon 100 F. At 8 o'clock in the evening the child began to bleed freely from the right naris, and after ineffectual attempts on the part of the mother to control this I was called and reached the house at 11 o'clock. I soon succeeded in controlling the hemorrhage, which I judged was septic in character. The next day, the 13th, not being satisfied with the condition presenting, I again asked for a bacteriologic report, and was told then that a few Klebs-Loeffler bacilli could be found in one of the cultures. The child was immediately given 5,000 units of antitoxin and such supportive treatment as was regarded necessary. The urine was found to contain considerable albumin. The morning of the 15th 3,000 units more of antitoxin were given. Temperature at this time (rectal) was 101.6 F, and pulse 76. The child raised herself up about 12 o'clock that day, collapsed and died.

CASE 4—Miriam M., aged 14, schoolgirl, sister of the previous two patients, developed sore throat and temperature of 102 F the night of January 14. The next morning a creamy exudate was found on both tonsils, with considerable faucial congestion but no extension to surrounding parts. The exudate on the tonsils in this as in the previous cases, had nothing characteristic of diphtheria about it. Five hundred units of antitoxin had been given the child the night before, and 3,000 units additional were now given her. There was no nasal discharge. Cultures from the child's throat showed an abundance of streptococci with some staphylococci, but positively no diphtheria bacilli. Swabs were taken morning and evening, thus giving a control. There was no albumin in the urine.

This case ran practically the same course as that of the boy Charles, who had received no antitoxin, and this patient (Miriam M.) was apparently free from the effects of the disease forty-eight hours afterward. Repeated examinations of the cultures grown in this case made by several competent men showed an entire absence of diphtheria bacilli.

This series of cases in one family had some very peculiar features. Every effort was made to ascertain the presence of diphtheria bacilli, and the cultures were made from swabs vigorously rubbed over the exudate in all the cases, and grown on Loeffler's blood serum mixture. Dr. B. W. Fontaine, who very kindly grew the cultures and made the bacteriologic examinations in his laboratory, was not contented merely with his examinations, but had several other men to study the slides with him. The case last reported ran the same course as that of the first case in the family, and the antitoxin could not be said to have exerted any influence on the course of the disease, for the duration of this case was no shorter than that of the boy who was not given antitoxin. In the case of the child who died, there was an entire abatement of the symptoms for one day, and it seems as though in this case the mixed infection here presented was characterized by an inhibition of the growth and effects of the diphtheria bacilli due to the preponderance of streptococci. This has been observed in other cases, and it has been my experience, and I am sure that of others that where we have this virulent type of mixed infection a fatal termination is almost inevitable, and antitoxin given even in the earliest stages lacks the potency which seems to be associated with its use in infections with the pure Klebs-Loeffler bacillus. Kyle says, "The presence of streptococci, in addition to the *Bacillus diphtheriae*, augurs ill for the patient because to their effects are due the complications of the more malignant character." The fatal termination in this case was probably further assured

by the violent septic hemorrhage which doubtless weakened the child considerably, although this was not shown by the condition of her pulse the next day. Considering the readiness with which diphtheria bacilli are grown on proper culture media, the ease with which they are isolated, and also the repeated examinations of the cultures in these cases, there could be no question of faulty technique causing failure to find the specific bacillus in those cases here reported as failing to reveal this. Furthermore, there was nothing characteristic of diphtheria in the tonsillar exudate, and the clinical course of the disease in all but the fatal case was unusually short, while the temperature ran much higher than commonly is found in diphtheria, and in none of these cases was there any membrane whatsoever, nor extension from the tonsils, features diagnostic of diphtheria. The diphtheria infection in the case of Corinne M. probably was secondary in its effects to the streptococcus infection, and the virulent mixed infection very likely would have been fatal under any circumstances.

Before passing from this series of cases, I should also mention that a young nurse, probably 19 or 20 years of age, who, for about forty-eight hours, was with the patient who died, was taken sick the night that she left the house, and the following morning had an exudate on her tonsils similar to that of the cases reported. The serum tube inoculated by me from her throat grew immediately a culture of streptococci with a few diphtheria bacilli. This girl received, I believe, about 800 units of antitoxin, but was practically over the attack in forty-eight hours.

CASE 5—R. T. C., male, aged 34, came to my office with temperature of 100 F, a slight exudate on both tonsils, and some glandular enlargement. Culture showed streptococci and staphylococci, the former predominating. This patient did not stop work, and was free of fever in about two or three days after I first saw him.

The next case is more interesting.

CASE 6—History—Miss Virginia G., aged about 30, seen through the courtesy of Dr. Edward D. Mitchell, began to have severe sore throat about a week previous to the day that I first saw her. She had some pain in the right side of her chest a week before this, but no symptoms of pneumonia. Her fever had been running as high as 104 F in the afternoons, but was usually lower in the mornings. The throat pain was quite severe, being more pronounced in the right side, and reflected to the ear. The back of the head and neck on this side were very tender.

Examination—This showed considerable faucial congestion, with some edema of the soft parts—edge of velum palati, etc. There was no exudate on the tonsils at all. The right cervical glands were enlarged and tender, and the least pressure seemed to cause excruciating pain. The temperature at the time that I first saw the patient was 102 F.

Course of Disease—Ice to the back of the neck and a fever mixture were ordered and the next morning the temperature was normal and the patient felt decidedly better. The following day, however, I received a message that she was suffering greatly, even more than she had at any time previously. On calling at the house I found the throat in the same condition of congestion as before and the glands just as swollen and painful. Her temperature was 101 F. While there was nothing showing in the throat other than congestion, I swabbed the affected side and inoculated a culture tube. The same treatment as previously advised was continued. The next day the patient was decidedly better, and convalescence was uninterrupted. The culture showed a mixed growth of streptococci and staphylococci.

Marschik¹ recently reported from Chiari's clinic a case of septic hemorrhagic pharyngitis occurring in a man 54 years of age, which ended fatally in fourteen hours, and in which the streptococcus was found in almost pure culture. While ordinarily we do not expect a streptococcus infection of the throat to terminate fatally, yet we are not justified, apparently, in giving a favorable prognosis in any of these cases, since we can not determine when the condition may assume a malignant type. Bearing this statement out is the history of a case recently seen by me in consultation.

CASE 7.—History.—On March 10, 1909, I was asked by Dr. E. M. Holder to see Mrs. P., aged about 32, who had been under his care for about three weeks. Dr. Holder stated that when Mrs. P. came to him at first she had an eruption over her body which he regarded as a possible lues, and for which he gave her mixed treatment. There were also some rheumatic symptoms. This eruption disappeared, and a short while afterward the patient developed considerable glandular enlargement of the left side of the neck, there subsequently being some soreness of the throat. This enlargement was at first confined to the glands, but later involved the periglandular tissue, until it resembled an acute phlegmon. The patient had been having some fever and was slightly at times. She was sent to the Presbyterian Hospital the morning of the day that I saw her, and an incision was made by Dr. Holder through the most boggy portion of the involved area, but pus was not found. A few days prior to this a clear blister resembling pemphigus was noticed on one finger, but no other blebs were found. The patient was very much depressed, and seemingly in a grave condition from the sepsis.

Examination.—I found Mrs. P. in a lethargic, almost stuporous condition, but mentally clear. Her temperature was 99.4 F., with small, fast pulse. There was a large and brawny swelling of the glands and periglandular tissues of the left side of the neck, especially marked low down toward the clavicle. No fluctuation was detected anywhere. The throat showed no distinct peritonsillar swelling, and there was no exudate on the tonsil, although there was some edema of the uvula. I inoculated a culture tube with a swab which had been rubbed over the peritonsillar region of the left side of the throat, and the next morning received a report of a rich growth of streptococci.

Course of Disease.—This patient was being given supportive treatment by Dr. Holder, and nothing else was regarded as advisable. The case went on to a slow recovery. The prostration in this case was very marked, and an excellent illustration of the virulency of the infection.

Memphis Trust Building.

ADVERTISING BY PHYSICIANS*

JOSEPH GRINDON, M.D.

ST. LOUIS

A discussion of the ethics of advertising may at first seem superfluous to the respectable physician, or, at least, not to interest him personally. "A gentleman," he will say, "knows how to conduct himself without consulting a written code. Reputable physicians do not advertise, and therefore nothing more need be said on the subject." But we are sometimes called on to pass judgment on the acts of others, and then the dictates of a sound conscience, which are sufficient to determine one's own conduct, require to be formulated into rules, in order that we may proceed with that order essential to justice. But, besides, is it true that reputable physicians do not advertise? Is it not rather true that all physicians, consciously or unconsciously, willingly or unwillingly, advertise and are advertised?

Is the trail of the serpent, then, over us all? Not at all. For there is objectionable advertising and unobjectionable advertising, differing in form, but still more in intent, and the gulf between the charlatan and the true physician exists, not from the fact that the one advertises and the other does not, for both do, but from the kind of advertising practiced by each.

I can almost see the hot wave of anger mounting to the faces of some of my honest friends at these words, while they can hardly suppress the vigorous protest rising to their lips. But, my dear doctor, have you never had a card printed with your name, address and office hours? I admit that it was not intended for advertising purposes, but is it not at least potentially an advertisement? Do not your name, occupation and address appear in the city and telephone directories? That, you say, is merely for the convenience of your patients, but, none the less, there it is, plain for all men to see. Have you no sign on your door or window? You don't mean it as an advertisement, maybe, but it is one, all the same. And your biggest and best paying advertisement is your title of "Doctor" by which you are everywhere addressed.

Let us then consider what is proper in the way of advertising, and what is not. And first let us see in what set terms the wisdom of our profession in this country has from time to time expressed itself on this subject. It will be useful not only to cite the text of the national pronouncement now recognized, but also from codes and similar formulas in force in earlier times and in various parts of the land, inasmuch as we wish to know not only the written law which can be invoked to-day, but the sentiment of the American profession on this subject from its earliest expression. We need not be surprised if we find the oldest and the newest in close accord.

The earliest dictum on this subject I have found is one by the New York State Medical Society. On Feb. 27, 1823, "A System of Medical Ethics" was reported to that body by a committee appointed for that purpose, and was adopted.¹ We read under heading "Quackery," Division II, Section 6:

Public advertisements or private cards, inviting customers afflicted with defined diseases; promising radical cures; engaging for no cure, no pay; offering advice and medicines to the poor, gratis; producing certificates and signatures even from respectable individuals in support of the advertiser's skill and success, and the like, are all absolute acts of quackery, which medical institutions should always repress and punish by the rejection or expulsion of those who commit them.

The American Medical Association, at its first annual session, in May of 1847, adopted a "Code of Ethics,"² which continued as its formal expression until superseded by the "Principles of Ethics" in 1903. We read in the "Code," Article I, Section 3:

It is derogatory to the dignity of the profession to resort to public advertisements, or private cards, or handbills, inviting the attention of individuals affected with particular diseases—, publicly offering advice and medicine to the poor gratis, or promising radical cures, or to publish cases and operations in the daily prints, or suffer such publications to be made; to invite laymen to be present at operations; to boast of cures and remedies; to adduce certificates of skill and success, or to perform any other similar acts. These are the ordinary practices of empirics and are highly reprehensible in a regular physician.

1. Tr. Med. Soc. State of N. Y., Volume for 1807-1831, p. 222. Reprinted 1861, p. 282.

2. First published in the Transactions xviii, 523. Before that it appeared in a small pamphlet.

4. Monatsschr. f. Ohrenh., xliii, No. 1.
* Read before the St. Louis Medical Society, Feb. 6, 1909.

The Code of Ethics was adopted by the St. Louis Medical Society June 18, 1850.

The Massachusetts Medical Society, Feb. 4, 1880, adopted a Code of Ethics.³ Its provisions on the subject of advertising are very brief and concise:

He (the physician) should not . . . advertise himself or his practice in public print.

In 1882 the Medical Society of the State of New York adopted a code of its own, varying from the code of the American Medical Association in some important particulars, chief among which was the matter of consulting with irregular practitioners. This "New Code," as it came to be called, was adopted February, 1882, by a vote of 52 to 18. That year the delegates of the state society were refused admission to the American Medical Association by the Judicial Council, and remained out until 1906. This led to the formation of the New York state and county medical associations in affiliation with the American Medical Association.

In the matter of advertising, however, the New Code was, if anything, more stringent than the old. I reproduce the section in question, placing in italics the words not found in the old code. The final sentence of the latter, beginning, "These are the ordinary practices of empirics," was omitted from the New York document:

It is derogatory to the dignity and interests of the profession for physicians to resort to public advertisements, private cards or handbills, inviting the attention of individuals affected with particular diseases, publicly offering advice and medicine to the poor, *without charge*, or promising radical cures, or to publish cases and operations in the daily prints, or to suffer such publications to be made; *or through the medium of reporters, or interviewers or otherwise, to permit their opinions on medical or surgical questions to appear in the newspapers;* to invite laymen to be present at operations; to boast of cures and remedies; to adduce certificates of skill and success, or to perform other similar acts.

The American Medical Association adopted, March 28, 1891, certain "ordinances" supplementary to the code, and binding equally with the original document. Among these were the following:⁴

Resolved, That it shall not be proper for specialists publicly to advertise themselves as such, or to assume any title not specially granted by a regular chartered college.

Resolved, That private handbills, addressed to members of the medical profession, or by cards in medical journals, calling attention of professional brethren to themselves as specialists, be declared in violation of the Code of Ethics of the American Medical Association.

These ordinances, now superseded by the Principles of Ethics, have been widely disregarded, as is evidenced by the frequent use of the words "practice limited to" such a specialty on the cards of men generally and properly rated as in good standing.

At the meeting of the American Medical Association at Saratoga Springs in 1902, a resolution was offered in the House of Delegates⁵ to the purpose that the revision of the code approved by the council of the New York State Medical Association (in affiliation with the American Medical Association) be examined by a committee and reported on in 1903. The resolution being adopted, a report was accordingly submitted the year following, differing widely in some particulars from the letter, although not from the spirit of the old code. The report says:⁶

The caption, "Principles of Medical Ethics" has been substituted for "Code of Medical Ethics" . . . the committee deemed it wiser to formulate the principles of medical ethics without definite reference to code or penalties. Large discretionary powers are thus left to the respective state and territorial societies to form such codes . . . as they may consider proper, provided, of course, that there shall be no infringement of the established ethical principles of this Association.

These "Principles" were unanimously adopted by the House of Delegates, at New Orleans, on May 7, 1903. The language of the principles in reference to advertising is as follows:

ART. 1. SEC. 7. Advertising methods to be avoided.

It is incompatible with honorable standing in the profession to resort to public advertisements or private cards inviting the attention of persons affected with particular diseases; to promise radical cures; to publish cases or operations in the daily prints, or to suffer such publications to be made; to invite laymen (other than relatives who may desire to be at hand) to be present at operations; to boast of cures and remedies; to adduce certificates of skill and success, or to employ any of the other methods of charlatans.

The St. Louis Medical Society, besides subscribing from the first and ever since to the Code, Ordinances and Principles of the American Medical Association, has from time to time enacted by-laws of its own, prohibitive of advertising and related methods. Thus we read in the "Constitution and By-laws," published in 1896, as follows:

BY-LAWS, ART. 1. SEC. 13: No person holding any patent, or part thereof, for medicines or secret remedies for disease, or who shall, by publication in newspapers or otherwise, announce his pretensions to superior qualifications in any particular disease or diseases; or who shall resort to public advertisements, or private cards or handbills, inviting the attention of individuals affected with particular diseases; or publicly offer advice or medicine to the poor, gratis; or promise radical cures, or publish cases or operations in the daily prints, or suffer such publications to be made, or invite laymen to be present at operations, or adduce certificates of skill and success, or perform any other similar acts, shall be eligible to (or) retain membership in this Society.

In 1900 (By-laws, Art. XXIV, Sect. 2) the above language was repeated almost exactly, and there was added to the list of reprehensible practices "the announcement of the use of secret methods of cure" and "paying or offering any salary, bribe or commission in return for patients procured, or accepting the same, or employing others to do any of these things, shall, among other things, be considered gross misconduct in the sense of the preceding section."

Our present by-laws (adopted October, 1907) do not enumerate various forms of misconduct, but specifically endorse the Principles of Ethics of the American Medical Association in the following language:

BY-LAWS, CHAP. 1, SEC. 5. Misconduct.

Any member guilty of gross misconduct, either as a physician or a citizen, or of violating any of the provisions of this Constitution and By-laws, or the Principles of Medical Ethics of the American Medical Association, shall be liable to censure, suspension or expulsion.

Having thus reviewed the letter of the law as formulated in various times and places, let us seek to penetrate its true spirit, and thus learn in what ways it is proper, if any, for the physician to bring himself to the attention of the public.

Advertisements, or let us say notices, addressed by the physician to the public, may be divided into five classes.

3. *Post. Med. and Surg. Jour.*, 1880, cil. 256.

4. *Tr. A. M. A.*, 1869, xx, 28.

5. *THE JOURNAL A. M. A.*, 1902, xxxviii, 1649.

6. *THE JOURNAL A. M. A.*, 1903, xl, 1379.

1. Those which are not only uncondemned by the Principles of Ethics, but which are in use everywhere and by the most conscientious physicians. These consist of signs usually not exceeding a foot or two in length, in modest colors, suspended in front of the office, or affixed to a wall or door, or inscribed on a window, setting forth the doctor's name, sometimes with the addition of his hours; and of cards similarly modest in appearance and statement, such cards never to be promiscuously distributed. Even such cards are employed rather as convenient memoranda of the physician's address and hours than as advertisements, although they may unquestionably be applied to the latter purpose by overzealous friends and admiring patients into whose hands they fall.

2. Those not condemned by the Principles of Ethics and in use in certain communities and by certain individuals of unquestioned respectability, while avoided by others. They consist of simple business cards inserted in lay publications, containing the same matter as the ordinary office card. Such announcements were in general use in this country a generation or two ago, are still in common use by practitioners in the smaller towns and in many large cities by practitioners having a foreign-speaking clientele. They are virtually obsolete among English-speaking metropolitan physicians. It might be said of these that they are rather intended as memoranda of address, hours, etc., to those already secured as patrons than to attract new practice. The use of such announcements in certain places and under certain circumstances may be indiscreet, but does not call for formal condemnation.

3. Those not specifically condemned by the Principles of Ethics, but manifestly in contravention of its spirit, and as such universally deprecated by consistent and worthy physicians. Such practices come under the general condemnation of the Principles of Ethics, being included within the meaning of the closing phrase of Art. 1, Sect. 7, "any of the other methods of charlatans." The distributing of cards on the street or from door to door, the use of very large or very showy signs, or the distributing of reprints of medical articles to prospective patients or other laymen might be cited as examples, although the last-named practice will often come directly under the condemnation of "boasting of cures and remedies."

4. Advertisements, veiled in form, oftenest consisting of accounts of cures, operations, alleged discoveries, and so forth, ostensibly written by newspaper reporters, but really furnished by the physician, verbatim or in substance. These are condemned by the Principles of Ethics, are the most dangerous and vicious of all forms of advertising, and arouse the disgust and contempt of all honest men, whether in the medical profession or out of it, inasmuch as they necessarily contain an element of untruth, seeking to conceal their true character, and to secure for their perpetrators the wages of prostitution, while striving to shield them with a cloak of respectability.

Another class of newspaper articles may be mentioned in this connection, varying widely in their true nature and intent, and ranging all the way from some which are not only proper but deserving of commendation, down to those which narrowly escape an infraction of the bare text of the law.

We refer to articles in the lay press dealing with topics of medical interest, or presumably written from a medical standpoint. The subject is a delicate one, for,

while it is usually easy for the discerning reader to discover the true animus of an article, whether, on the one hand, inspired by a genuine desire to instruct and benefit, or, on the other, designed to impress the reader with the writer's attainments and thus secure him as a possible patient, it none the less remains difficult to define each sort in categorical terms. Sometimes the diagnosis is made clear by the presence of pathognomonic symptoms of moral malignancy, such as a more or less flattering half-tone of the eminent professor, a list of his titles and honors, references to his performances and achievements, or again by the frequent recurrence of the first person singular. These characteristics are, however, avoided by the shrewder veiled advertisers.

Rules of general application in deciding as to the true character of such productions may perhaps be deduced from a classification according to their subject-matter.

Articles and interviews by physicians in the lay press, apart from accounts of cases and operations, which need not further detain us, are usually of one of three kinds:

1. Those containing advice.
2. Those discussing scientific points.
3. Those discussing the diagnosis or treatment of some individual case which has gained notoriety.

The advice imparted in the first class of articles may be such as any one easily can and therefore should, if need be, obtain from his regular adviser, and which therefore should not be distributed gratis and unasked. As examples we may cite such titles as "How to Reduce Your Weight" and "What to Do When Baby Has the Measles."

Or the advice may be so generally applicable as to possess real value, and at the same time be such as the reader would probably not obtain from his regular attendant, because he would not think of applying for it. As examples we may cite articles on preventive medicine, such as the prophylaxis of tuberculosis or typhoid, the precautions to be observed in times of epidemic or during extremes of heat and cold, the importance of vaccination, and of the medical inspection of schools; instruction as to first aid in drowning, heat-stroke, poisoning and the like; as to the dangers attendant on the habitual use of alcohol and other drugs, and, again, the exposing of dangerous charlatans and nostrums.

It seems evident, therefore, that of the class of articles conveying advice, some, as those of the sort first mentioned, are, to say the least, open to grave suspicion, while others, such as were last enumerated, may be of great benefit to the community, be purely altruistic in purpose, and therefore should receive the hearty commendation of the profession. This is especially true when they are written by one who is well informed in the matter, and with the ability to put his thoughts on paper, whose recognized position in the profession is such as to lend weight to his utterances, and who has already attained to such honors and rewards as to lift him above any suspicion of harboring sordid motives. The giving of instruction to the public is, indeed, specifically insisted on by the old "Code" and the "Principles" in almost identical terms.

The Principles of Medical Ethics says:

CHAPTER 3. The duties of the Profession to the Public.

Sec. 1 [in part]: They [physicians] should also be ever ready to give counsel to the public in relation to subjects especially appertaining to the profession, as on questions of sanitary police, public hygiene and legal medicine.

Sec. 2 [in part]: It is the province of physicians to enlighten the public in regard to quarantine regulations, to the location, arrangement and dietaries of hospitals, asylums, schools, prisons and similar institutions; in regard to measures for the prevention of epidemic and contagious diseases.

Sec. 4. It is the duty of physicians who are frequent witnesses of the great wrongs committed by charlatans, and of the injury to health and even destruction of life caused by the use of their treatment to enlighten the public on these subjects, and to make known the injuries sustained by the unwary from the devices and pretensions of artful imposters.

Contributions of the second class, those, namely, discussing scientific matters of general interest, are unobjectionable unless so written as to direct attention to the writer rather than to the subject-matter.

Articles falling within the third class, namely, those discussing the diagnosis or treatment of cases which have become notorious, or which affect eminent personages, will, as a rule, deserve the censure of the judicious, for it can not be urged that they serve any useful purpose. The discussion, if proper at all, should be reserved for the medical press, and is out of order in a lay publication, lying, as it does, outside of the sphere of the audience which it addresses. It is difficult even for the charitable-minded to see any purpose in such effusions, except the aggrandizement of the writer.

An opinion on an illness or injury, expressed by a physician who was at no time connected with the case, is not justified by the circumstance that the sufferer is a prominent personage, or that he lives in a distant place. Such public discussion of the diagnosis or treatment adopted for the patient of another practitioner, besides being necessarily based on incomplete and uncertain information, is in itself grossly indelicate and in violation of common justice and common courtesy. These latter considerations are perhaps not germane to the subject of this paper, but it may well be suspected that a public deliverance so unnecessary and so indefensible is prompted by selfish motives. Some of my older hearers may recall certain peculiarly revolting examples of this particular brand of indecency in connection with the sufferings of the lamented President Garfield.

To this same class belong expressions in the public prints as to the sanity of noted criminals. To say nothing of the crying injustice of trying men for their lives in the columns of a daily journal, a casual glance at such learned (?) pronouncements will usually show them to be either garbed in polysyllabic technicalities unintelligible to the non-medical reader, or to deal with matters concerning which the lay mind can not correctly judge, since no subject within the periscope of our science is so difficult, so involved, so beset with subtleties and uncertainties, and so purely a matter for the specialist, as is that of psychiatry. The least grave charge that can be made against "interviews" of this sort is that they argue a weak yielding to the importunities of a reporter and to the alleged curiosity of the public as to matters which are none of their concern, inasmuch as they lie beyond their powers of comprehension. As a matter of fact, however, such articles are generally "interviews" in name only, having been carefully written out by the learned expert who hopes thus to keep within the limelight.

Another debatable form of publicity is that of the antemortem biographical notice, often accompanied by a portrait, appearing in bound collections of sketches of "distinguished" citizens, or perhaps in the Sunday edition of a metropolitan paper.

If it concern some individual of such real eminence that his personality has become a thing of interest to the intelligent public, such publication may be excusable, inasmuch as its real and its avowed purpose are then the same. Such a notice is not an advertisement, because it does not seek to create notoriety, but is its consequence. If such notoriety be the unsought fruit of genuine achievement of great value, the publication of a notice or picture may be beyond cavil. Often, however, names and faces so paraded have little claim to distinction.

It may be impossible here in every case to draw a hard and fast line between what is allowable and what is not. Practically, however, if the truth can be learned, the question may be settled, at least in the affirmative, by a simple test: Was the insertion contingent on the payment of a fee, direct or indirect? If so, it is an advertisement, although perhaps not actionable under the letter of our law. The latter point is debatable. The unworthy character of the act is not debatable. It does not follow from what was said above that a notice inserted free of charge is, therefore, not an advertisement.

5. Last among the classes of advertisements by physicians, using the last term somewhat loosely, are the flagrant, undisguised, paid advertisements, generally displaying an alleged picture of the "doctor," his chin either concealed by a patriarchal beard or appearing as a naked plain flanked by flowing side-whiskers; or the portrait may be that of a victim; the accompanying text may be simply mendacious, or again obscene or criminal. These we need not discuss, further than to say that there is something about their boldness which begets a feeling distantly allied to respect, which the more covert performances of their timid admirers and would-be imitators could never do, just as there is a lurid halo about the memory of Jesse James or of Billy the Kid, which is not shared by the Sicilian ladrones who picked the pockets of the dead at Messina.

It will be noted that in the foregoing attempt at an analysis of the subject, I have taken the term "advertising" in a somewhat restricted sense, namely, that of reading-matter of one sort or another addressed to the public. I realize that there are many other things, spoken words and actions, which are in a sense advertisements, but apart from the necessity of fixing certain bounds to a subject, and limiting its discussion within these, I feel that a classification of the wider sort mentioned into its orders, families, genera and species, would involve a dissertation on the whole moral law, and is made unnecessary by the commandment, "Thou shalt love thy neighbor as thyself."

I have also left untouched the matter of advertisements of the physician's learning and skill addressed to and intended for the profession. This subject is a very difficult one, while the evils it includes are not of the sort which cry to Heaven, for this reason, if no other, that the medical audience addressed is better able to take care of itself than is the lay public.

To sum up, we may conclude that any notice emanating from a physician which seeks to secure for him an unfair advantage over his fellows, or which departs so widely from established usages as to compromise his dignity, is an objectionable advertisement, and that the greater the pains taken to conceal its true character the deeper is its damnation.

Clinical Notes

A CASE OF UNDIAGNOSTICATED BRAIN ABSCESS*

AUGUSTUS A. ESHNER, M.D.
PHILADELPHIA

Abscess of the brain is not a common affection and it is not rarely overlooked. It is almost invariably secondary to suppuration elsewhere, although it may be a sequel of direct injury to the head. Inflammatory disease of the middle ear is probably the most common causative factor. The symptoms are essentially those of a tumor of the brain plus those of a toxic-infective process. The diagnosis may be exceedingly difficult, if not impossible, without a knowledge of the etiologic agency. In the case to be reported it should have been possible to recognize the condition and to afford relief through surgical measures.

History.—A woman, aged 35, was admitted to the nervous ward of the Philadelphia General Hospital, Feb. 5, 1909, complaining of headache, pain in the back and legs and abdomen, with nausea, vomiting and pain in the left ear. The illness was said to have been of two weeks' duration and to have set in with headache, pain in the lower extremities and back, together with nausea and vomiting. There had also been diarrhea and chills, fever and sweating. The patient went to bed for a day, then arose, and again had to go to bed two days before admission to the hospital. There had been a discharge from the left ear for three months. On entrance into the hospital the temperature was 97 F., the pulse 70, the respiration 25. The temperature soon rose to 102, but it gradually declined to the normal, while the pulse at no time rose above 88 and the respiration above 25. The patient complained of headache and suffered from nausea and vomiting.

Examination.—The pupils were contracted and equal and reacted to light and in accommodation. The ocular movements were well performed and there was no nystagmus. The activity of the facial muscles was preserved and alike on the two sides except that the creases produced on wrinkling the forehead were more pronounced on the right side than on the left. The knee-jerks were slightly increased, but the remaining reflexes, as well as sensibility and the action of the sphincters, were normal. There was no noteworthy abnormality of the thoracic or abdominal viscera. There was no discharge from either ear. There was some mental confusion. The urine contained a trace of albumin and a few hyaline casts. On suspicion that the case was one of typhoid fever the patient was transferred to the medical ward, where she complained of intense headache and insomnia and exhibited marked restlessness. Intelligence was obtunded. On examination no discharge from either ear was found, nor was there tenderness over the mastoid process, even on strong percussion. The urine contained albumin and hyaline and granular casts. The hemoglobin percentage was 85 per cent., the number of red corpuscles 4,800,000, and the number of leucocytes was 10,000 in the cubic millimeter. The agglutination test for typhoid fever was made twice, and in each instance yielded a negative response.

Course of Disease.—On February 11 the patient stated that her headache was less severe than it had been and that she was resting better. On February 12 drowsiness developed, with irritability, the patient resenting interference. On February 14 she complained of nausea and on two occasions vomited a considerable amount of greenish, watery, sour-smelling fluid. The drowsiness increased, while the headache persisted in undiminished degree. Death took place abruptly early on the morning of February 16.

Autopsy.—A large amount of turbid, greenish pus of foul odor, together with a small amount of diffuent brain tissue, escaped when the calvarium was removed and the adherent dura on the left side incised. The middle and lower temporal convolutions of the left cerebral hemisphere were the seat of an

abscess communicating with a sinus in the petrous portion of the adjacent temporal bone, and this in turn was the continuation of a larger abscess in the middle ear. The bony portion of the internal ear was also involved in the destructive process. The kidneys were the seat of acute inflammation; the myocardium was involved in fatty infiltration and fatty degeneration, and the liver was the seat of fatty infiltration.

The case was at the beginning supposed to be one of typhoid fever, but the early decline of the temperature, together with the absence of the specific agglutinating reaction, negatived such a diagnosis. The absence of pain, tenderness and swelling about the ear and of discharge, as well as of cerebral symptoms of a localizing character, especially when taken in conjunction with the slight changes in temperature, pulse and respiration, diverted attention from the head, although the persistent and intense headache, the nausea and vomiting, the inequality in action of the two sides of the forehead, and the mental impairment, especially in conjunction with the leucocytosis, the history of previous ear disease and of chills, fever and sweating, should have awakened suspicion of the real condition. The state of the urine also contributed to the confusion, as uremia had to be considered as a possible cause. It is to be regretted that an examination of the eyegrounds was not made, as a unilateral lesion would have been a most significant finding.

1019 Spruce Street.

A DELICATE TEST FOR BILE IN THE GASTRIC CONTENTS

ALBERT WOLDERT, M.D.
TYLER, TEXAS

In making chemical analyses of the gastric juice siphoned off one hour after a test meal, I have frequently observed that the specimen before and after filtration would have a decided greenish tint, suggesting either bile or *gastrosia fungosa* (mold in the stomach) and on testing some of this filtered gastric juice for bile by the nitrous acid method, I have often been surprised that no reaction would be given.

On April 17, 1909, after siphoning off the gastric contents from a patient I observed that the specimen had a grass-greenish tint. I allowed the gastric contents to pass through some ordinary white filter-paper, and on testing this filtered gastric juice for bile by the nitrous acid test I obtained no reaction. The filter-paper, especially the upper edge, was stained quite green in color, and I could not persuade myself that bile was not present, or else that the case was one of *gastrosia fungosa*. The filter-paper was removed from the funnel, and that portion of the gastric contents, consisting of mucus and remnants of test breakfast, which did not pass through the paper was scraped off. This filter-paper was laid aside to dry during a period of several days. Four days later, on April 21, this dried filter-paper still had a greenish appearance, especially around the edges. On moistening these greenish areas with nitrous acid I observed the play of colors characteristic of the bile reaction, the green color first changing to a faint reddish tint, which lasted a few seconds, then being followed by blue, and after two to five minutes changed to a brownish tint. Thinking that the same reaction could be perhaps obtained by using the filtered gastric contents, I then passed some of it back through another piece of white filter-paper, and, when it was thoroughly dry, applied the nitrous acid test as before, but obtained no reaction, owing, no doubt, to the fact that the viscid

* Read before the Philadelphia Neurological Society, April 23, 1909.

bile had not passed through the filter-paper in sufficient quantity to respond to the nitrous acid test.

In testing the gastric contents for bile, one should allow the gastric juice to pass through white filter-paper, and when it has become dry one should then apply the nitrous acid test to this filter-paper. Instead of testing the filtered gastric contents: otherwise bile in the stomach may escape detection. This reaction is best observed in a somewhat shaded portion of the room.

HAT-PIN IN THE MALE URETHRA

T. L. HAZZARD, M.D., PITTSBURG, PA.

The report by Dr. B. Clark Hyde in *THE JOURNAL*, March 12, 1909, p. 885, of a case of shawl-pin in the male urethra reminds me of a similar case which happened in my practice in 1886.

Mr. —, aged about 40, married, came into the office stating that he was carrying a hat-pin about in his urethra. Examination demonstrated that something was there. He admitted that he had been masturbating with the hat-pin when it escaped his grasp and got away. He had consulted several physicians: the result was considerable laceration of the urethra, a meatus enlarged by incision, quite a bit of swelling and some hemorrhage. The bead end could be felt in the membranous urethra and the sharp end had engaged in the upper urethra, about an inch from the meatus. Realizing the futility of fishing for it with forceps, I at first introduced a small pipette into the penis, hoping to maneuver so as to engage the sharp end of the pin and so remove it. This I was unable to do, possibly because I did not persist in trying, as a simpler method suggested itself, nearly the same as that pursued by Dr. Hyde. I bent the penis at a right angle to the direction of the pin, thrust the sharp end of the latter through the urethra and skin, then drew it out until the bead stopped it. Reversing the direction, the bead end was pushed out through the meatus and the pin easily withdrawn. The patient did not return, so I can not state the later history.

Therapeutics

SCIATICA

The sciatic nerve is one of the frequent locations of nerve pain, and is perhaps more frequently the location of a neuritis or a perineuritis than any other nerve of the body. All possible causes of the condition must be sought for and found or excluded, and before a general condition, or a condition of the blood, is decided to be the cause of the neuralgia or inflammation, all local reasons should be excluded.

A frequent cause of sciatica in women is pressure on the nerve in the pelvis, either from uterine displacements, uterine enlargements, tumors or inflammation that has extended and caused pressure.

Constipation, with fecal matter remaining long in the lower bowel, is also a not infrequent cause of sciatica, and such a condition of the loaded sigmoid is a not uncommon cause of left-sided sciatic pain.

Gout and rheumatism certainly are many times the cause of sciatic neuritis.

Exposure to wet and cold, especially when the feet become wet and chilled, or sitting on cold stones, or long sitting on hard-bottomed chairs may be the initial cause of a sciatic neuritis.

Pain in the lumbar muscles, lumbago or lumbar myalgia, is often followed by pain in one or the other, or both sciatic nerves: or both conditions may be present at once. In fact, frequently when there is no evident abdominal or pelvic excuse, a lumbago is followed

by pain in a sciatic nerve. A not infrequent cause of a lumbago is too lax springs and a too comfortable bed. This is especially true when the person is of heavy weight. A stiffening of the bed springs and a straightening of the bed will often be sufficient alone to stop this kind of pain which is so frequent, and also so frequently extends to the sciatic nerves.

A weakening of the plantar arch and an attempt of the person involuntarily so to step and stand as to relieve the ache in the ankles and feet will cause abnormal muscle tension, even of the thighs, and a sciatic pain can be caused from this reason, to say nothing of the frequent pain in the knees from this cause.

Uricacidemia, and even an increased acidity of the urine, with bladder irritability, is often a concomitant condition with sciatica. The sluggish circulation due to an imperfect heart action or to a varicose condition of the leg may be a predisposing cause of sciatic pain. It is hardly necessary to mention the occasional causes of sciatica, as diabetes, malaria, syphilis and hip-joint or knee-joint disease.

Consequently, before beginning any local or general treatment for sciatica, the patient should be carefully examined and any local cause found, the circulation investigated, the urine analyzed, and the intestinal digestion and activity learned. It should also be determined whether the pain is due to neuralgia, i. e., a simple irritation of the sciatic nerve, or whether there is an actual neuritis or perineuritis, which may be determined by excessive tenderness, pain on stretching the nerve (as by thoroughly extending the leg) or by a beginning anesthesia in any part of the distribution of the nerve.

It is not necessary to urge the necessity for removing local pressure, if such has been found, before it could be expected that the sciatica or the neuritis could be made better. Free elimination from a calomel, castor oil, or saline purgative, and subsequent daily free movements of the bowels is certainly a large factor in the successful treatment of sciatic trouble. The character of the diet should be determined by the condition of the patient. If the patient needs nutrition, the most nutritive diet possible should be given, and, in fact, perhaps hyperalimentation given. On the other hand, if the patient is plethoric, has been a high liver, eating largely of proteids, especially meats, a vegetable and limited diet for a time, at least, is the best. If the circulation is impaired, it should be aided. If the circulation is good, plenty of water should be given to aid the eliminative process by the kidneys. Hot daily tub baths, a Turkish bath twice a week, or a body hot-air treatment twice a week, are all adjuvants in the treatment of sciatic inflammation that are far ahead of medicinal treatments. The body hot-air treatment is most efficacious when rheumatism is the cause of the condition, and no treatment is perhaps more successful. This is also especially true when there is kidney insufficiency. The promotion of the circulation in the skin and the increase of the excretory ability of the skin is a large factor in the benefit derived from such treatment.

Occasionally the attack of sciatica comes on suddenly, but generally it is gradual in its development, and the longer it has persisted the more difficult is it to cure; consequently, sciatica, even in mild form, should not be neglected.

It is probable that the shooting pains down the sciatic nerve, momentary perhaps in their duration, are caused by contractions of the pyriformis muscle, which compresses the sciatic nerve. It is also probable that

this muscle sometimes becomes irritated and inflamed and keeps up, by its contractions, pressure on the sciatic nerve. If such pressure is more or less continuous, sciatic neuritis could be caused. This condition being surmised or suspected, local treatments aimed at relieving the spasm of this muscle should be instituted. Among such measures may be included static wave currents, mechanical vibration and sparks from a static machine locally applied to the region of the foramen through which the sciatic nerve leaves the pelvis. Also sometimes beneficial is the application of dry heat to this part, and perhaps best by the reflected heat and light of a strong electric light.

Sometimes counter-irritation along the course of the sciatic nerve by momentary localized applications of the galvanic electric current with the positive pole active, or painting along the course of the nerve with iodine, or electric light bath treatment to the whole course of the nerve, or dry cupping along the course of the nerve and repeated on successive days, will abort a beginning neuritis. In an ordinary case of sciatic neuralgia, if the cause is removed, the neuralgia will cease.

If beginning neuritis or perineuritis is suspected or diagnosed, absolute rest of the limb on a level, hard bed, with electric light applications or dry heat applications, with the administration of alkalies or salicylate, and the general management of the bowels above outlined, may still abort the inflammation.

If, on the other hand, an actual neuritis is present, there is nothing that will shorten an attack so much as a long splint from the axilla to the heel, to give permanent fixation and rest. If a splint is used for this purpose, the bandage which binds it should be removed at least once, and perhaps better twice, a day and the limb gently flexed once or twice so that the joints will not become stiffened. The length of time such a splint should be used is determined by the amount of pain and the rapidity with which the inflammation improves. No fixed rule can be established. Another method of fixing and treating a limb so affected is by long sand bags, which may be put into the oven and rendered very hot, and changed as often as they become cool. Such applications give rest to the limb and constant dry heat. If such heat is not applied, the limb should be swathed in cotton and bandages, as warmth is very essential in all cases of neuritis.

When the pain is intense, and especially if periodical contractions of the muscles occur (which, however, are best prevented by the long splint), injections of morphin must be given. But perhaps nothing will prevent the necessity of such injections more than the ability to give the leg perhaps, but better the whole body, hot-air treatment, which, of course, can only well be done in an institution. The amount of morphin that is needed and the frequency depends on the pain. Such frightful pain can not be endured, and, if not stopped by other means, must be stopped by morphin.

Sometimes the injection of cold water or of a small dose of cocain directly into the nerve sheath in the region of the sciatic notch will cause almost instant cessation of the pain. If cocain is used hypodermatically, the dose would be from 0.008 to 0.015 gram ($\frac{1}{8}$ to $\frac{1}{4}$ of a grain), but it should not be often repeated, and it does not seem to be very advisable treatment. If cold water is used and reaches the sheath of the nerve and distends it in this region, of course, it will stop the sensations below, and such treatment sometimes precludes the necessity of the administration of morphin.

The coal-tar analgesics are only of temporary benefit in mild cases, are never of benefit when there is severe pain, and; as the need for an analgesic is so frequent in sciatic neuritis, great debility would be caused by such repeated use of them. Ordinarily, therefore, they should not be used in sciatic neuritis.

There is no really good reason for using atropin hypodermatically in sciatic neuritis. The pain of neuritis comes from the main trunk of the nerve and is distributed more or less to all its branches. Atropin only dulls nerve pain when that pain is due to peripheral irritation. If atropin is used in conjunction with morphin it does nothing but inhibit the narcotic and quieting effects of the morphin, and more morphin is required. Also, if the dose of morphin must be repeated for severe pain, the discomfort of the patient is increased, the restlessness is increased, and the secretions are decreased by the frequent repetition of atropin.

Osmic acid has been used subcutaneously in sciatica to the amount of 1 c.c. (15 minims) of a 1 per cent. solution. Perhaps the best method is to dilute the 1 c.c. (15 minims) of the 1 per cent. solution with sufficient water to allow of a series of injections, from five to ten, into the nerve trunk throughout its course, a few drops being instilled into the nerve sheath at each puncture. This method is, of course, painful, although it may be followed by good results, but the favorable action is possibly largely due to the "acupuncture" treatment and to the distention of the nerve sheath (nerve pressure) from the water. Therefore, if the sheath of the nerve is to be pierced at all, it would seem best to do this at the sciatic notch and instill sufficient water to produce anesthesia below.

It should be understood that a sciatic neuritis is like any other neuritis, and, therefore, will first grow worse, reach its acme, and then gradually and slowly become better, with anesthetics, pain, and more or less paralysis. The patient should be told that a long, tedious process is before him, and that no exact time limit to the duration of the inflammation can be promised.

After the acute condition is past, massage, possibly gentle counter-irritation, faradic stimulation of the muscles, or other electric or hydrotherapeutic measures may be used to bring the leg back to normal function.

It should be again emphasized that probably the most efficient means of shortening the inflammation in the nerve and hastening recovery is by the hot-air treatment.

As soon as the active symptoms have ameliorated, and especially if there is chronic sciatic pain, thermocautery treatment along its course, and repeated once in five days, causes efficient counter-irritation and frequently a cure.

Paralyzed muscles should be treated with such electric and massage treatments as is usual in other paralyses.

If the cause of the cured neuritis was a systemic one, such treatment should be carried out and persisted in as would tend to prevent a recurrence.

Tonics, especially iron, are indicated; fresh, warm air, if possible, and a convalescence long enough to restore complete health to the injured leg, are aids to a permanent cure.

As above stated, too much care can not be taken to positively cure an inflammation such as sciatic neuritis, which tends to recur and often causes permanent disability.

New and Nonofficial Remedies

SINCE THE PUBLICATION OF THE BOOK "NEW AND NONOFFICIAL REMEDIES, 1909," THE FOLLOWING ARTICLES HAVE BEEN ACCEPTED BY THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION. THEIR ACCEPTANCE HAS BEEN BASED LARGELY ON EVIDENCE SUPPLIED BY THE MANUFACTURER OR HIS AGENT AND IN PART ON INVESTIGATION MADE BY OR UNDER THE DIRECTION OF THE COUNCIL. CRITICISMS AND CORRECTIONS TO AID IN THE REVISION OF THE MATTER BEFORE PUBLICATION IN THE BOOK ARE ASKED FOR.

THE COUNCIL DESIRES PHYSICIANS TO UNDERSTAND THAT THE ACCEPTANCE OF AN ARTICLE DOES NOT NECESSARILY MEAN A RECOMMENDATION, BUT THAT SO FAR AS KNOWN IT COMPLIES WITH THE RULES ADOPTED BY THE COUNCIL.

W. A. PUCKNER, SECRETARY.

(Continued from page 1499)

FORMIC ACID—*Acidum Formicum*.—*Acidum formicicum* (Pharm. Helvetica, edit. 4; Pharm., Germ. edit. 4).

Formic acid is a liquid containing 24-25 per cent. of anhydrous formic acid (HCOOH).

Formic acid is a colorless liquid possessing a sharp acid odor and taste. It has a specific gravity of 1.058-1.061. With lead acetate, formic acid produces a white crystalline precipitate. On warming with silver nitrate a gray turbidity and with mercuric chloride a white turbidity is produced. A solution (1-10) after the addition of a few drops of nitric acid should yield no precipitate with silver nitrate or barium chloride; and after neutralizing with ammonia water calcium chloride or hydrogen sulphide should produce no precipitate. If 1 Cc. formic acid is mixed with 5 Cc. water and 1.5 Gm. mercuric oxide (yellow) and heated on the water bath there will follow an evolution of gas leaving a mixture which when filtered will yield a filtrate which should not react acid (acetic acid). Five Cc. formic acid should require 27.6 Cc. to 28.8 Cc. normal alkali for neutralization, denoting a content of 24-25 per cent. by weight of 254-265 Gm. anhydrous formic acid per liter. The titrated solution should yield no burned or sharp odor (Pharm. Helv. and Pharm. Germ.).

Action and Uses.—The actions resemble those of acetic acid, but it is more volatile, more irritant and more antiseptic. Formic acid is much more resistant to oxidation, in the body, than the other organic acids, and is therefore excreted to a large extent as formates, in the urine. These have an irritant action on the kidneys and urinary tract, and are diuretic. Large doses cause methemoglobinemia, but the toxicity is quite low. It has no effect on the general circulation or on the motor system, as has been claimed. It has been lauded in a great variety of disorders, but there is no good evidence that its internal use produces any benefits other than psychical. Its external use as a counterirritant is rational, but it possesses no special advantages.

Dosage.—Internally, 1-20 drops of the 25 per cent. acid, largely diluted; or 0.1-0.25 Gm. (1½-4 grains) of sodium formate. Externally usually in a solution containing 1 per cent. of the absolute acid in alcohol or diluted alcohol.

BERBERINE HYDROCHLORIDE—*Berberinae Hydrochloridum*.—The hydrochloride, $\text{C}_{20}\text{H}_{17}\text{NO}_4\text{HCl} + 2\text{H}_2\text{O}$, of an alkaloid obtained from *Hydrastis canadensis* and *Berberis vulgaris*.

Berberine hydrochloride occurs as bright yellow acicular crystals or amorphous powder, slightly soluble in alcohol to which it imparts a deep yellow color. It is soluble in 300 parts cold water, but dissolves more easily in hot water.

An aqueous solution of berberine or its salts treated with chlorine or bromine water produces a blood red color. Bromine water in excess precipitates the reddish-brown berberine tetrabromid-hydrobromide— $\text{C}_{20}\text{H}_{17}\text{NO}_4\text{Br}_4\text{HBr}$, which is converted by washing with alcohol or heating to 100° to the yellow-brown berberine dibromide-hydrobromide $\text{C}_{20}\text{H}_{17}\text{NO}_4\text{Br}_2\text{HBr}$.

Ammonium sulphide precipitates from an alcoholic solution of berberine sulphate the polysulphide $(\text{C}_{20}\text{H}_{17}\text{NO}_4)_2\text{H}_2\text{S}_8$ which crystallizes in brown-black needles.

Berberine solutions even if very dilute when treated with potassium iodide solution yield a yellow precipitate of berberine hydroiodide.

Action and Uses.—Given by mouth, it acts as a bitter stomachic. Very large doses, although not fatal, cause diarrhea, tremors, general weakness, low blood pressure (from depression of vasomotor center and of cardiac muscle), rapid pulse (depression of vagus endings) and respiration. Recovery is slow. Nephritis may be present. Subcutaneous injection kills by paralysis of respiration, with symptoms of asphyxia and paralysis. It has been used as a bitter tonic, against diarrhea and the vomiting of pregnancy and as a febrifuge.

Dosage.—0.06 Gm. to 0.3 Gm. (1 to 5 grains). As much as 20 grains have been taken without obvious effects besides a loose stool.

EMETINE HYDROCHLORIDE—*Emetinae Hydrochloridum*.—*Methyl-cephaeline*. The hydrochloride, $\text{C}_{15}\text{H}_{21}\text{N}_2\text{O}_2\text{HCl} \cdot 3\text{H}_2\text{O}$, of a base found together with cephaeline in *Cephaelis Ipecacuanha*.

Emetine hydrochloride occurs as a white crystalline powder, soluble in water and alcohol. A freshly prepared concentrated solution of ammonium molybdate in concentrated sulphuric acid is colored brown by emetine; this color changes to violet when a drop of concentrated hydrochloric acid is added. The general alkaloidal reagents precipitate emetine, even from dilute solutions. Alkalies precipitate emetine from aqueous solutions of its salts.

Action and Uses.—Similar to Ipecac, but relatively more nauseant and less emetic, and causing relatively somewhat less renal irritation, but more cardiac depression.

Dosage.—Expectorant, 0.005-0.01 Gm. (1/12-1/6 grain). 0.01-0.02 Gm. (1/6-1/3 grain) causes emesis, but cephaeline is preferred as an emetic.

KERATIN—*Keratinum*.—A proteid substance which forms the chief part of horns, hoofs, feathers, wool, etc.

To prepare keratin horn shavings are macerated for some days in a mixture of equal parts of ether and alcohol, decanting the liquid and washing the residue with warm water. The washed shavings are then treated with an acid solution of pepsin at 40° C. (104° F.). After further washing with water the residue is dried and powdered.

Keratin occurs as a brownish yellow powder or in transparent white or grayish white scales, tasteless and odorless. It is soluble in concentrated acetic acid, caustic alkalies and ammonia; but insoluble in water, alcohol, ether, dilute acetic acid or acid pepsin solutions. It is decomposed by long boiling under pressure forming a turbid solution with the liberation of hydrogen sulphide. Boiling with dilute sulphuric acid converts it to leucine, tyrosine and other products. On ignition it emits the odor of burning feathers and the remaining carbon is very difficultly burned. On complete combustion the ash should not exceed 1 per cent. 24 hours' digestion with 15 times its volume of ammonia or glacial acetic acid solution at 25°-40° C. (77°-104° F.) should not leave more than 0.3 per cent. insoluble matter.

Uses.—For coating pills to pass the stomach unchanged.

RED GUM—*Eucalypti Gummi*.—*Eucalyptus* gum. *Eucalyptus Kino*.

Red gum is an exudation from the bark of *Eucalyptus rostrata*, Schlecht, and other species of *Eucalyptus*.

Red gum occurs in small dark reddish brown opaque and more or less dusty pieces which yield a pale red powder. It is usually collected from artificial incisions. When chewed it is tough, and colors the saliva red. Water dissolves 80-90 per cent. Its chief constituent is tannic acid, to the extent of 47 per cent.

Action and Uses.—Red gum is an active astringent. It is used as an active astringent in sore throat, diarrhea and in catarrhal affections of various mucous membranes. Largely used in the form of lozenges where an astringent is needed in throat affections.

Dosage.—0.1 to 0.3 Gm. (2 to 5 grains).

SODIUM OLEATE—*Sodii Oleas*.—Sodium oleate, $\text{NaC}_{17}\text{H}_{33}\text{O}_2$, is the sodium salt of oleic acid.

Sodium oleate is obtained by neutralizing sodium hydroxide with oleic acid.

Sodium oleate is a white solid, which crystallizes from absolute but not from aqueous alcohol. When heated it melts and burns leaving a residue of sodium carbonate. It is soluble in about 10 parts of water, in about 20 parts of alcohol, and in about 100 parts of boiling ether. When dissolved in water it is partly decomposed (hydrolysed) into oleic acid and sodium hydroxide; hence its aqueous solution has an alkaline reaction to phenolphthalein; its solution in strong alcohol is neutral to this indicator. It is precipitated from its aqueous solution by saturation with sodium chloride.

Acids separate from its aqueous solution oleic acid, which collects at the surface of the liquid, in an oily layer. If a solution of 5 Gm. of sodium oleate, in 50 Cc. of water be mixed with 3 Cc. of tenth-normal oxalic acid solution, the subsequent addition of a few drops of phenolphthalein test solution should not produce a pink coloration.

An aqueous solution of sodium oleate (1 in 20) should remain unchanged in color upon the addition of ammonium sulphide test solution; and upon acidulating another portion of the solution with hydrochloric acid and filtering, the filtrate should remain unchanged in color when an equal volume of hydrogen sulphide test solution is added and the mixture is allowed to stand well stoppered in a warm place for half an hour (absence of metallic impurities).

Action and Uses.—Sodium oleate is antacid and mildly laxative. It is commonly added to laxative pills. It has been claimed without any definite evidence that it is especially useful in disease of the biliary tract.

Dosage.—0.12 to 1.3 Gm. (2 to 20 grains).

1. This preparation should not be confounded with the preparations sold as "Acid sodium oleate" or "Sodium Oleate, acid" which are mixtures of sodium oleate and free oleic acid, containing from about 5 to 30 per cent. of the latter.

THE BIOLOGIC ANALYSIS OF GENERAL SENSATION

In view of the great importance of so-called general sensation, or common sensation, in clinical work, particularly in the diagnosis of nervous and visceral diseases, it is rather surprising that we have so often been content with a very uncritical analysis of this sensation complex.

Nearly twenty-five years ago Gaskell from the physiologic side and His from the embryologic side established the now classical four-root theory of the composition of the spinal nerves, recognizing in each pair somatic and visceral motor and somatic and visceral sensory components. More recently Sherrington¹ has elaborated a very fruitful physiologic analysis, dividing the sense organs (receptors) of the body into: (1) interoceptors, or visceral sense organs of the digestive tract and its derivatives; (2) exteroceptors, or somatic sense organs of the outer body surfaces for impressions coming from the outside world, and (3) proprioceptors, sense organs of the muscles, joints, tendons, etc., adapted to report to the central nervous system the exact state of contraction, tension, etc., which these organs experience during function and thereby assisting in the coordination of all somatic movements.

The chief importance of this analysis lies in the emphasis placed on the type of response characteristic of the several receptors. The interoceptors are related through the sympathetic nervous system with visceral muscles; the exteroceptors through the superficial nerves, including the nerves of higher sense, with the somatic or skeletal muscles; the proprioceptors through the deep sensory nerves with reflex arcs leading back to the body musculature. Otherwise expressed, the interoceptive reflexes are visceral responses to visceral stimuli; the exteroceptive sensori-motor system is the apparatus by which the body is able to make adaptive responses to outside stimuli, and the proprioceptive system is for the internal regulation of the exteroceptive mechanism. Naturally, the peripheral and central conduction paths of these three systems have played a dominant rôle in the evolution of the architecture of the nervous system, and the accurate knowledge of these conduction paths is of great clinical importance.

The detailed analysis of the sensory components of the cranial nerves of vertebrates and their cerebral centers has been effected by a series of researches of the past fifteen years, chiefly at the hands of American comparative neurologists.² It seems probable that from the primordial nerves of general sensation of the lowest animals the first differentiation was into visceral (interoceptive) and somatic (exteroceptive) nerves and that each of these was then further subdivided. Some members of both systems of nerves in lower vertebrates are sensitive to chemical stimuli; but in man the chemical sense (taste) seems to be chiefly, if not wholly, represented in the visceral system, its fibers ending in company with more generalized visceral nerves in the nucleus of the fasciculus solitarius. Smell is probably a still more highly differentiated member of the same system.

The exteroceptive and proprioceptive functions of the somatic sensory system were doubtless contemporaneously differentiated and each was early subdivided into different kinds of sense qualities. The proprioceptive nerves include several sensory types whose functions (for the most part wholly unconscious) are concerned with equilibration, muscular coordination, etc., such as the nerves of muscle spindles, tendons, articular surfaces and deep sensibility in general. The nerves of the semicircular canals are the most highly specialized members of this system (Sherrington). The exteroceptive nerves include contact receptors, serving the sensations of pressure, touch, temperature, etc., and distance receptors (organs of vision and hearing). The contact sensations of the skin, which are frequently classed uncritically in clinical practice in a single category as "general sensation," have been analyzed in a valuable way by the recent clinical and experimental work of Henry Head and his colleagues.

THE PATHOGENESIS OF URINARY CALCULI

Since the demonstration of the infectious basis of gallstone formation we have had many contributions to our knowledge of their pathogenesis, chemistry and structure, which have cleared up this subject to a gratifying degree. Urinary calculi have, during the same period, received less attention from the pathologists and chemists. Just as Naunyn worked out the principles of gallstone formation to a satisfactory conclusion which has stood the test of time, so Ebstein, in his classical monograph on urinary concretions, developed many of the fundamental conceptions of this topic. He showed that the urinary calculi are not simple conglomerations of crystals, but possess an organic framework of characteristic structure, the product of pathologic processes in the urinary tract, in which the crystalline salts are imbedded and held together. Just what conditions are

1. The Integrative Action of the Nervous System. New York, 1906.

2. For summaries of this work see Johnston, The Nervous System of Vertebrates, Philadelphia, 1906.

necessary for the production of this complex deposit in the urine has not yet been fully determined, but a recent paper by Schade¹ seems to bring forward a reasonable theory of calculus formation.

He begins by pointing out a fundamental error in earlier considerations of this subject, namely, that of looking on the urinary constituents as existing in simple watery solution. In the light of physicochemical conceptions, urine is more complex than this. It contains always more or less of colloids, including under normal conditions especially the pigments, which greatly modify the solution of the crystalloids. The colloidal substances exist in the condition of colloidal suspension, and consequently present an enormous amount of surface area which has more or less adsorptive power for the crystalloids which are in true solution. When a considerable amount of adsorption takes place in this way, there results at the surface of each colloidal particle a zone in which the crystalloids are more concentrated than elsewhere, and which will always serve as the starting point of crystallization whenever the solution becomes oversaturated. It is because of this adsorptive power that colloids increase the solvent power of urine for uric acid, for the more of the slightly soluble uric acid that is withdrawn from the watery solution by adsorption into colloidal particles the more uric acid can the urine dissolve. When the crystalloid goes out of solution it will, therefore, form crystals or precipitates which are most intimately associated with the colloids, as we see when uric acid crystallizes out of urine taking with it the colloidal pigments by which it is adsorbed. Hence the complex colloidal stroma which is found in every concretion and even in every crystalline deposit which is formed in urine.

It is a well-known fact clinically that a urinary calculus is not nearly so soluble as a simple crystalline mass of the same chemical nature; otherwise we would be able much more easily to dissolve urinary calculi by merely changing the reaction of the urine according to the nature of the calculus. But it is only too certain that uratic calculi will persist in alkaline urine, and oxalate calculi will remain in acid urine without appreciable change. This insolubility Schade explains as due also to the colloidal matrix. If the calculi consisted merely of crystalline deposits, they would dissolve readily, for crystallization is a reversible process. Likewise if the colloid were one that formed reversible precipitates or gels, as mucin which precipitates with acids and redissolves in alkalis, urinary calculi would also be correspondingly soluble; but if the colloidal matrix is one that forms precipitates or gels that are not reversible, then resolution of the calculus is difficult.

Such a colloid is fibrin, and Schade found that he could produce experimentally with calcium salts and fibrinogen, masses of salts which became progressively harder and stonelike, and which had the same struc-

tural arrangement of matrix and crystals as is characteristic of calculi. Therefore, he urges the importance of inflammatory exudation in the formation of urinary calculi. Normal urine contains no irreversible colloids, and hence does not form concretions; but any inflammatory exudation taking place in any part of the urinary tract introduces fibrinogen, and conditions become suitable for the formation of irreversible deposits of any crystalloid with which the urine may at the time be saturated or oversaturated. Possibly other colloids may have the same property, but probably fibrinogen is the most important. Much of practical significance for the prevention and treatment of urinary calculi would seem to lie in these suggestions of Schade's, which point out some of the reasons for existing disagreement between theory and practice.

The solubility of concretions depends on entirely different laws from that of the simple crystalline deposits which never form concretions, yet hitherto we have attempted to find solvents for calculi on the basis of our experience with the solubility of simple crystalline formation, and have met with failure. Possibly a better understanding of the nature of calculus formation will help us toward the goal of solvent treatment.

A BRITISH COUNCIL ON PHARMACY AND CHEMISTRY

While it is possible that the medical profession of Great Britain has not been exploited by proprietary medicine promoters to quite the extent that has been the case in this country, yet the proprietary evil there is a serious and a growing one. That British medical men are beginning to wake up to this fact is evident from one of the "notices of motion" put forward by the South-Eastern of Ireland Branch of the British Medical Association, to be acted on at the annual meeting of the association to be held in July.

This notice proposes "that the council be requested to appoint a *Materia Medica* Committee, whose duty it will be, with such professional aid as they can summon to their assistance, to investigate and pronounce on the uses and properties of all drugs which shall be used by the profession; and, in view of the grave injury inflicted on the public and on the profession alike by the present wholesale introduction of drugs by mere commercial firms, whereby the ground is being cut from under our feet, and the gullible public are induced to accept nostrums on the sole strength of mere assertions, that the hospitality of our museum and the pages of our *Journal* shall both be shut out from giving any further aid to the wholesale advertisements of drugs and preparations, the virtues of which have too often no existence save in the mendacity of their introducers."

It will be seen that the proposed *Materia Medica* Committee is practically identical with the Council on Pharmacy and Chemistry of the American Medical Association. The need of such a committee is evident;

1. Münch. med. Wchnschr., 1909, lvi, 3.

should it be appointed, it will do much to limit the sale of nostrums as "ethical proprietaries." Since the work of the Council and the campaign carried on by THE JOURNAL have given American nostrum makers a substantial set-back, it has been the policy of these gentlemen to transfer their activity to the other side of the Atlantic. When a similar campaign is waged in the British Isles, the discomfited manufacturers will have no place to go. The Anglo-Saxon countries have been the last to regulate the traffic in nostrums, but the field of operation for this business is slowly but surely narrowing.

In passing, it might be said that when the suggested body begins its work, the *British Medical Journal* will, perforce, lose some of its regular advertisers. Nevertheless, this loss of revenue to the association's organ will be more than compensated by the gain to the profession generally.

A STUDY IN THE INCONSISTENCY OF THE ANTI-VIVISECTIONISTS

The inconsistency in operation of the basic emotional activities which are the springs of human action is well brought out in an editorial in *La Follette's Weekly Magazine* for April 10, entitled "False Mercy and Real Cruelty." "If a horse had been tied on the street in Washington on inauguration day," says *La Follette's*, "its owner would have been arrested for cruelty." Yet, the article goes on to point out, on the same day 800 men of a Massachusetts coast artillery organization were kept shivering and stiff for two hours or more in the storm, waiting for the parade to move, then marched for five hours in a blizzard, and quartered without beds on the floor in a cold and miserable armory. It is scarcely to be wondered at that 100 of them became ill, mostly with pneumonia, and that a score or so died. Some years ago on a similar occasion 75 men died from a similar cause. "If 75 sparrows had been tortured for five hours for somebody's pleasure," comments *La Follette's*, "the conscience of the nation would have been shocked." Verily, a sensitive conscience is an elastic term when applied to communities, and recalls to mind the distinction finely drawn by Jane Austen in "Sense and Sensibility."

It is but natural that the article should pass on to the consideration of an analogous inconsistency—that of the supersensitive souls who would fain abolish all experimentation on animals. Says *La Follette's*, "The animals, of course, are not experimented on for pleasure, or to make a parade, but for the sake of the knowledge and cure of diseases. The animals are put under ether or chloroform, and the operations are usually painless. The average dog used in educating physicians and surgeons dies with infinitely less suffering than that endured by any one of the Massachusetts soldiers as he shivered the night through in a bedless armory—to say nothing of the marching and pneumonia—and he dies

for a good and, to most people, a sufficient reason. Dogs, cats, rabbits, and guinea-pigs should not be killed, even under anesthesia, wantonly or for no reason. But if the question is not whether the animal experiments shall stop, but whether the animals experimented on are to be dumb animals or men, women and children, then we may ask whether human beings are not worth more than dogs or guinea-pigs.

"The antitoxin that cures diphtheria, the Pasteur hydrophobia treatment, the Koch tuberculin test for consumption, the knowledge that protects us from disease generally, the prevention of disease in live stock, the use of ether, chloroform and cocaine, which make dentistry and surgery painless, all have been discovered by and depend on animal experiments. Had it not been for them we should not yet have learned that the blood circulates, or the use of the heart, or the functions of the nerves; we should still be calling in magicians to cast out the devils when we are ill, and hanging the witches believed to torment us with pains and aches. Protect the animals—certainly. But do not force science to practice on us rather than on them. Protect the horses—certainly. But remember that a man is worth more than many horses. Don't be so falsely merciful that you reach real cruelty."

It is an admirable thing when a man of public affairs, possessed of an unusual capacity for "straight talk," is imbued also with a breadth of view in the search for knowledge concerning that whereof he talks, that shall enable him to use it wisely and well.

RESIDUAL TYPHOID FEVER

Not long ago it was generally considered that practically all cases of typhoid were due to polluted drinking water, and some enthusiasts even ventured the statement that the amount of typhoid in a city affords a very fair idea of the purity of its public water supply. The acquisition of new data, however, is bringing about in this field, as in so many others, what might almost be styled a reversal of opinion. Not that there is any doubt on the part of any competent authority as to the large part sewage-contaminated water has played and is still playing in the transmission of typhoid fever, but there is no longer a tendency to minimize or to ignore other causes. One really astonishing circumstance is that after an infected water supply has been purified or replaced by a purer source the residuum of typhoid fever is still very great. A recent Harvey lecturer has drawn attention to the fact that in most cities in the United States, even after a pure water supply has been secured, the typhoid fever death rate has remained at least five or six times as high as in European cities of similar rank.¹ Point has been given to this situation by the well-known experience of the city of Washington, D. C., which has had the keen disappointment of seeing its typhoid rate remain prac-

1. Jordan: THE JOURNAL A. M. A., Feb. 15, 1908, 493.

tically stationary after the installation of a well-built and efficiently operated filter plant.

Longley² has now thrown some new light on the Washington problem by showing that there is a reasonable doubt whether even in years past the Potomac water supply was really responsible for the general prevalence of typhoid fever in the District of Columbia. Sedimentation of the river water, which has been believed by many sanitarians to explain the fluctuations in typhoid fever in Washington, is considered by Longley, after careful analysis of the data, to have had little or no share in bringing about the conditions observed. There is, in his opinion, no marked relation between the period of sedimentation and the typhoid death rate in Washington. This conviction is strengthened by the remarkable parallelism which Levy and Freeman have shown to exist between the typhoid fever curves in Washington and in Richmond, Va. In Richmond the water supply has remained unchanged during a period of nearly thirty years, and yet the years of rise and fall of the typhoid death rate in the two cities coincide in a manner that suggests the operation of some common cause.

What explanation can be given for the non-water-borne typhoid fever? There is no doubt that a certain proportion of it can be accounted for by milk infection, by fly infection, by contact through the agency of carriers and in other ways with which recent investigation has made us familiar, but when all is said there is still an unexplained residuum. The proportion of typhoid not traceable to acknowledged sources of infection is apparently greater in some localities than in others. It is a tempting speculation that meteorologic conditions in some way influence individual susceptibility, but it can hardly be said that there is any strong evidence for this view. The coincidence in the typhoid curve in cities with dissimilar sanitary conditions might seem to support this hypothesis, but there are obviously other possibilities. The questions raised are certainly important and hardly to be dismissed as of theoretical interest only.

SMOKE CONSUMPTION

The unwholesome effect, psychical and physical, exercised by a sunless smoke-laden atmosphere has long been recognized. The crux of the problem has been to render smokeless combustion not merely experimentally possible, but commercially practicable. Smoke in cities is undoubtedly an immense extravagance for the community, having a deleterious effect on many marketable commodities, as well as on the health and strength of the inhabitants. It is a direct loss to the consumer of coal, too, for smoke means waste fuel. Yet the attempts to make smokeless combustion an actual, as well as a theoretical, economy to the one who pays the coal bills have been only partially successful in the past. It is

now asserted that the United States Geological Survey Experiment Station at Pittsburg, Pa., has succeeded in solving the problem and in that smoky city is now operating its plant absolutely without smoke, even though burning a coal considered refuse by the trade and costing, delivered at the station, 88 cents a ton. Moreover, over two hundred industrial plants in the larger cities of the country are now being operated without smoke, and with a gain in economy. The solution of the whole problem appears to depend, not on any particular form of furnace, but on the simple principle that "stokers or furnaces must be so set that the combustion shall be complete before the gases strike the heating surface of the boiler"; otherwise sudden cooling, with checking of combustion, will ensue. Absolutely and invariably satisfactory results are said to depend on the installation of mechanical stokers, as the personal element in firing is too variable to be relied on. The report of the experts who had immediate charge of the government investigation will shortly be issued by the Geological Survey as a bulletin, which will doubtless prove valuable reading for sanitary medical officers and engineers. If it can be demonstrated that, as the Geological Survey maintains, "in 50 per cent. of the industrial plants of the United States more than 10 per cent. of the coal bill can be saved each year by the smokeless burning of coal, and 5 per cent. in the other plants," our cities will soon enjoy a purer air and a brighter sky than they have known for many a long day.

Medical News

ILLINOIS

Home for Nurses Donated.—James A. Patten has donated \$40,000 for the erection of a home for nurses of the Evanston Hospital. The structure will be connected with the main hospital building and will provide accommodation for 40 employees, including nurses and internes.

Hospital Appropriation.—The omnibus appropriation bill which passed the house early this week gives the State Board of Health \$46,000 for the free distribution of antidiphtheric serum throughout the state. The last general assembly appropriated \$30,000 for this purpose.—The State Board of Health has already been allowed \$4,000 for the free treatment of poor persons said to have been bitten by rabid animals or otherwise in danger from infection from hydrophobia.—The appropriations for the State Board of Health have been materially increased.

Personal.—Dr. George S. Duntley, Bushnell, has succeeded Dr. William E. Haines, resigned, as local physician for the T. P. & W. Railway.—Dr. Alvard G. Durkee, Pontiac, is at St. James Hospital, recovering from an operation for appendicitis.—Dr. Homer M. Little, East St. Louis, has returned after eighteen months abroad. While in Vienna, Dr. Little was elected secretary-treasurer of the American Medical Association of Vienna.—Dr. Albert N. Mueller has been appointed health commissioner of Rock Island, and Drs. William H. Ludwig, Michael J. O'Hern, Frank H. First and Joseph R. Hollowbush have been appointed members of the board of health.

Legislative Progress.—Senate Bill No. 214, to create a state board of osteopathy, was defeated in the house May 19, by a vote of 72 to 45. The "osteopathic lobby" claimed 100 votes for this bill, which at one time seemed assured of passage.—On May 21 the house set its disapproval on optometry by killing House Bill No. 576, which received only 28 of the 77 votes required for passage. There is still another osteopathic

2. Eng. News, Apr. 22, 1909, p. 493.

bill, Senate Bill No. 351, which passed the senate two weeks ago. This bill is even more objectionable than Senate Bill 214, and is at its second reading in the house. The State Board of Health and the legislative committee of the state medical society are of the opinion that this bill will not become a law.

State Medical Society Meeting.—The fifty-ninth annual meeting of the Illinois State Medical Society was held in Quincy, May 18-20. The following officers were elected: President, Dr. J. Leaming Wiggins, East St. Louis; vice-presidents, Drs. Clifford U. Collins, Peoria, and James E. Stubbs, Chicago; secretary, Dr. Edmund W. Weis, Ottawa (re-elected); treasurer, Dr. Everett J. Brown, Decatur (re-elected); councilors, Drs. Malcolm L. Harris, Chicago, Carl E. Black, Jacksonville, and Henry C. Mitchell, Carbondale; delegates to the American Medical Association, Drs. Frank Billings and Charles S. Bacon, Chicago, and James W. Pettit, Ottawa; alternates, Drs. Samuel C. Stremmel, Macomb, W. K. Newcomb, Champaign, Joseph R. Hollowbush, Rock Island, Edwin W. Ryerson, Chicago, and Alfred C. Haven, Lake Forest; committee on public policy, Drs. Robert B. Preble and William L. Baum, Chicago, and Carl E. Black, Jacksonville; committee on medical legislation, Drs. Charles J. Whalen, Chicago, Milton S. Marcy, Peoria, and Lewis C. Taylor, Springfield; and chairman of the medicolegal committee, Dr. Harold N. Moyer, Chicago. Danville was selected as the place of meeting for 1910.

IOWA

Personal.—Dr. James P. Lane has been elected health officer of Cascade. —Drs. John W. Reynolds and Cleve Coakley, Creston, and Dr. Oliver S. Barber, Kent, will open a hospital in Creston in a few weeks. —Dr. Henry J. Prentiss, professor of anatomy in the State University College of Medicine, Iowa City, has declined an offer to return to his former work at Bellevue Hospital Medical College, New York City.

Medical Women Meet.—At the twelfth annual meeting of the State Society of Iowa Medical Women, held in Dubuque, May 18, the following officers were elected: Dr. Lenna L. Means, Des Moines, president; Drs. Kate S. Harpel, Boone, and Pauline Myers-Townsend, Marshalltown, vice-presidents; Dr. Lena A. Beach, Cherokee, secretary, and Dr. Clara B. Whitmore, Cedar Rapids, treasurer. At the annual banquet Dr. Julia M. Donahue, Burlington, presided as toastmistress.

State Society Meeting.—At the fifty-eighth annual meeting of the Iowa State Medical Society, held in Dubuque, May 19-21, the following officers were elected: President, Dr. George E. Crawford, Cedar Rapids; vice-presidents, Drs. Nelson M. Voldeng, Cherokee, and Henry H. Clark, McGregor; secretary, Dr. Vernon L. Treynor, Council Bluffs; treasurer, Dr. William B. Small, Waterloo, and delegate to the American Medical Association, Dr. Arthur L. Wright, Carroll. Des Moines was selected as the next place of meeting.

KANSAS

New Hospital.—The Sisters of St. Agnes will establish and equip a hospital at Hays, to be owned by the sisters, but to be open to the sick of all creeds and beliefs.

Personal.—Dr. Joseph F. Wallace, Leavenworth, has been selected as superintendent of the sanatorium for tuberculosis which is being established by the Modern Woodmen of America, near Colorado Springs. —Dr. Sherman LaB. Axford, Burlington, has been appointed physician to the state penitentiary, Lansing.

Councilors Elected.—At the annual meeting of the Kansas Medical Society, the following councilors were elected: First District, Dr. Charles W. Reynolds, Holton; Second District, Dr. W. Preston Sterret, Kansas City; Third District, Dr. Hugh B. Caffey, Pittsburg; Fourth District, Dr. Ora P. Davis, Topeka; Fifth District, Dr. William E. Currie, Sterling; Sixth District, Dr. Archibald D. Jones, Wichita; Seventh District, Dr. F. M. Daily, Beloit; Eighth District, Dr. Oliver D. Walker, Salina; Ninth District, Dr. Chauncey S. Kenney, Norcatur; Tenth District, Dr. Ernest J. Beckner, Selden; Eleventh District, Dr. John A. Dillon, Larned; and Twelfth District, Dr. William F. Fee, Mead.

Society Meetings.—At the semi-annual meeting of the Southeast Kansas Medical Society, held in Parsons April 13, Dr. Edward B. Payne, Fort Scott, was elected president; Dr. Giles A. Blasdel, Garnett, secretary, and Dr. Millard F. Jarrett, Fort Scott, treasurer. —Physicians of Lynn county have effected a medical organization and elected the following officers: President, Dr. David E. Green, Pleasanton, and secretary-treasurer, Dr. Howard L. Clarke, LaCygne. —A committee from the Sedgwick County Medical Society appeared before the mayor of Wichita, April 22, and requested that the

secretary of the City Board of Health be given a position in the city hall, and that he take over the duties now devolving on the city physician and police surgeon and also the duties of city pathologist and bacteriologist, registrar of vital statistics, supervisor of sanitation of city schools, and local statistician for the State Board of Health.

KENTUCKY

Tuberculosis.—As the result of "Ten Cent Day," an idea conceived by Mrs. L. H. Wyman, Louisville, to raise funds for the work against tuberculosis, nearly \$2,000 was collected May 18, and it is anticipated that the total receipts will exceed \$3,000.

Damage Suits.—The Court of Appeals is reported to have ruled that Dr. Fouche W. Samuels, Louisville, pay Mary Willis damages of \$3,500. She claimed that he had left a sponge in her abdomen after laparotomy. —Judge Gordon May 19 gave instructions to the jury to find for the defendant in the case of Annie Edelen against Dr. Edgar W. Stokes, Louisville, who was sued for \$5,000, the plaintiff alleging that the defendant had failed properly to treat a fracture of the wrist.

Personal.—Dr. Lewis S. McMurtry, Louisville, has had conferred on him the degree of LL.D. by his alma mater, the Tulane University of Louisiana. —Drs. Clyde A. Eckler, Dry Ridge, Joseph L. Price, Sherman, and Americus V. Menefee, Williamstown, have been appointed members of the Grant County Board of Health, and Dr. Menefee has been made health officer of the county. —Dr. John Wood, assistant physician at the Central Kentucky Hospital for the Insane, Lakeland, resigned May 18, on account of ill health.

LOUISIANA

Site Purchased for Sanitarium.—The Hicks homestead, with about twelve acres of land at Shreveport, has been sold to the Sisters of the Incarnate Word for \$30,800. On this site will be erected the new Schumpert Memorial Sanitarium, to cost \$10,000, in memory of the late Dr. T. Edgar Schumpert.

Hospital Report.—At the annual meeting of the board of trustees of the Eye, Ear, Nose and Throat Hospital, New Orleans, April 20, the present administration was re-elected by unanimous vote. The total number of patients treated during the year was 7,838, or 1,147 more than for the preceding year, distributed as follows: Eye department, 3,552; ear, nose and throat department, 4,191; dermatological department, 95. Included in these were 686 emergency cases. The total number of consultations for the year was 53,687, an increase of 9,731 over last year. The maximum daily number of patients was 297, and the maximum number of new cases 74. During the year 1,657 operations were performed.

Society Meetings.—At the annual meeting of St. Landry Parish Medical Association, held in Opelousas, April 15, Dr. Robert G. Hawkins, Palmetto, was elected president; Dr. Paul Foster, Lewisburg, vice-president; Dr. L. Lazaro, Washington, secretary; Dr. William R. Boudreau, Washington, treasurer, and delegates to the state society, Drs. L. Lazaro, Washington, and J. C. Vidrine, Villeplatte. —Claiborne Parish Medical Society, at its annual meeting at Homer April 13, re-elected the following officers: President, Dr. Joseph W. Day, Homer; vice-presidents, Drs. Phillip Gibson, Homer, James F. Simpson, Athens, and Lee T. Waller, Haynesville, and secretary-treasurer, Dr. William L. Stone, Homer. —At the April meeting of Bienville Parish Medical Society Dr. Shelton I. Colvin, Gibsland, was elected delegate to the state medical society.

MARYLAND

County Association Meeting.—The annual meeting of Baltimore County Medical Association was held in Towson, May 20. Dr. Bennet F. Bussey, Cockeysville, was elected president; Dr. H. J. Jarrett, Towson, vice-president; Dr. Richard C. Massenburg, Towson, corresponding secretary; Dr. Josiah S. Bowen, Mount Washington, recording secretary; and Dr. William L. Smith, Sherwood, treasurer; and Drs. H. Lewis Naylor, Pikesville, and L. Gibbons Smart, Lutherville, were elected delegates to the Medical and Chirurgical Faculty of Maryland. The retiring president, Dr. Richard F. Gundry, Catonsville, in his address, made an urgent plea for the care of the indigent insane of the state.

Baltimore

Commencements.—The address at the commencement exercises of the University of Maryland, May 31, will be delivered by Dr. John A. Wyeth, New York City, who will also

receive from the university the honorary degree of LL.D.—At the annual commencement exercises of Baltimore Medical College, May 25, a class of 57 was graduated. Hon. J. Charles Linthicum presented the prizes, and ex-Governor Warfield delivered the address to the graduates.

Personal.—Dr. J. Canby Robinson has returned after a year in Germany.—Dr. Thomas S. Cullen sailed for Europe May 21.—Dr. Thomas H. Buckler will spend the summer abroad.—Dr. Samuel C. Chew has recovered from his recent illness.—Dr. Daniel W. Cathell has been elected president of the Baltimore Eastern Dispensary.—Dr. John C. Hemmeter has been named as one of the committee of patrons for the dedication of the monument to Michael Servetus, in Vienne, near Lyons, France, August 14.

Money for Charities.—As the result of a charity congress held by the Baltimore Judaic Union, \$1,400 was realized, which will be devoted to the establishment of a free dispensary in East Baltimore.—By the will of Miss Frances Donaldson, the Church Home and Infirmary received a bequest of \$5,000 for the endowment of a bed.—Harry E. Meyer has given \$10,000 to the Jewish Home for Consumptives, to be used for the erection of an additional cottage on the grounds of the institution near Baltimore.

MASSACHUSETTS

Gift to Hospital.—By the will of the late Miss Elizabeth Fay Brigham, Brookline, \$1,500,000 has been bequeathed to establish the Brigham Hospital for Incurables.

Wednesday Half Holiday.—The physicians of Lawrence, Methuen, Andover, and North Andover, have decided almost unanimously to close their offices on Wednesdays at 1 p. m., beginning July 1.

Bequests.—By the will of Mrs. Effa E. Brown, East Kingston, filed May 12, a bequest of about \$30,000 is made to the Lawrence General Hospital.—By the will of the late Dr. Frank W. Draper, Brookline, the income of the estate is eventually to be paid to Harvard University.

Personal.—Dr. Elmer E. Southard, Danvers, has been appointed pathologist to the Massachusetts Board of Insanity.—Dr. Robert W. Lovett has been appointed assistant professor of orthopedic surgery, Dr. Charles A. Porter, assistant professor of surgery, and Dr. Edward H. Nichols has been re-appointed assistant professor of surgical pathology in Harvard Medical School.

Carnation Day.—As the result of "Carnation Day" in Lynn, on which 27,000 carnations were sold for the benefit of the Day Camp for Consumptives, Swampscott, \$2,750.08 was raised. The camp will be opened as soon as the buildings can be put in condition for the reception of patients. On account of the success of the attempt, the committee has decided to establish the second Saturday in May in each year as "Carnation Day" for the benefit of the camp.

State Medical Society Meeting.—The one hundred and twenty-eighth annual meeting of the Massachusetts Medical Society will be held June 15 and 16 in Boston. The sectional meetings will be held in the Medical Library on the Fenway on June 15. In the evening the Shattuck Lecture on "The Widening Sphere of Medicine" will be delivered by Dr. Edward W. Taylor, Boston, and at the close of the lecture, a reception will be given to the president. On the second day, the annual discourse will be given by Dr. James G. Mumford, Boston, and at the close the annual dinner will be served.

Alumni Day at Harvard.—Alumni Day was celebrated at Harvard Medical School, May 20. In the evening the triennial dinner occurred, at which ex-President Eliot urged the necessity of a campaign of education so that the people may see vivisection and "new superstitions" in the right light. Lieutenant Governor Frothingham extended a welcome on behalf of the Commonwealth to the visitors from various parts of the country, and lauded the medical men holding state positions in Massachusetts. President Lowell, of Harvard, in his talk, stated that what the medical school of Harvard needed and should have, was a larger student body. Dr. William Osler, Oxford, England, advised that Harvard be remodeled on the lines of the medieval universities of Bologna and Padua. He thought the average age for Harvard medical graduates, 24, was too advanced, and should not be more than 23. He believed Harvard Medical School to be only half finished, as it had no hospital attachment. There should be a hospital as great as the school itself, and it should be a part of the university. Dr. Henry A. Christian, dean of the school, asked the cooperation of every alumnus in improving the institution. Major General Leonard Wood, U. S. Army, an alumnus of the school, delivered an address on what the med-

ical profession is doing in Porto Rico, Cuba, and the Philippines, and credited the profession with doing more than any other class excepting school teachers, to reconcile the people of the islands to American institutions. He urged young graduates to serve a while in the Army in the insular possessions to perfect their knowledge of tropical diseases, and finally endorsed the suggestion of the dean for the establishment of a professorship of tropical diseases in the university.

Elections.—At the annual meeting of Worcester North District Medical Society, held in Fitchburg, April 27, Dr. Eustace L. Fiske, Fitchburg, was elected president; Dr. William N. Cowles, Ayer, vice-president; Dr. Walter F. Sawyer, Fitchburg, secretary; Dr. Frederick H. Thompson, Jr., Fitchburg, treasurer; Dr. Luther G. Chandler, Townsend, commissioner of trials, and Dr. Atherton P. Mason, Fitchburg, librarian.—Hampden District Medical Association, at its annual meeting, held April 20, in Springfield, elected the following officers: President, Dr. Charles W. Jackson, Monson; vice-president, Dr. Harvey W. Van Allen, Springfield; secretary-treasurer, Dr. Richard S. Benner, Springfield; supervising censor, Dr. Vincent J. Irwin, Springfield; censors, Drs. George L. Taylor, Holyoke, Frederick S. Ward, Springfield, William C. Leary, Springfield, and J. H. Schneider, and commissioner of trials, Dr. Philip Kilroy, Springfield.—Plymouth District Medical Society, at its annual meeting, April 21, in Brockton, elected Dr. Frederick J. Ripley, president; Dr. Charles S. Millet, vice-president, and Dr. Alfred C. Smith, secretary, all of Brockton.—At the annual meeting of the Middlesex North District Medical Society, held in Lowell, the following officers were elected: President, Dr. Clarence A. Viles; vice-president, Dr. Omer P. Porter; secretary, Dr. Archibald R. Gardner; treasurer, Dr. Thomas B. Smith; librarian, Dr. Patrick J. Meehan, all of Lowell, and commissioner of trials, Dr. Frederick E. Varney, North Chelmsford.—At the annual meeting and dinner of the Dorchester Medical Society, April 28, Dr. Robert M. Merrick was elected president; Dr. M. Vassar Pierce, vice-president; Dr. Edward J. Brearton, secretary-treasurer.—The Berkshire District Medical Society, at its annual meeting, held in Pittsfield, April 29, elected Dr. Harry B. Holmes, Adams, president; Dr. Clifford S. Chapin, Great Barrington, vice-president, and Dr. Isaac S. F. Dodd, Pittsfield, secretary-treasurer.—Franklin District Medical Society held its annual meeting, May 12, in Greenfield, and elected Dr. Charles L. Upton, Shelburne Falls, president; Dr. Leroy A. Newton, Greenfield, vice-president; Harry N. Howe, Greenfield, secretary-treasurer, and Dr. Francis E. Johnson, Erving, commissioner of trials.

MICHIGAN

Accquitted on Charge of Perjury.—In the case of Dr. George A. Fritch, Detroit, charged with the commission of perjury in a death certificate, the charges were dismissed April 2, and the judge is said to have criticized the prosecutor severely from the bench.

March Mortality.—During March 3,524 deaths were reported, equivalent to an annual death rate of 15.6 per 1,000 of population. Among these were 696 infants under 1 year; 212 children from 1 to 4 years of age, and 1,180 individuals of 65 years of age or over. Among the important death causes were pneumonia, 355; tuberculosis, 256; cancer, 163; violence, 154; influenza, 71; meningitis, 47; diarrheal diseases of infants, 43; typhoid fever, 41; measles, 35; whooping cough, 32; diphtheria, 31, and scarlet fever, 14.

MISSISSIPPI

Hospital Notes.—The need of a central general hospital in the state has resulted in the organization of the Jackson Hospital and Sanatorium Company with a paid-up capital stock of \$50,000, by Drs. Julius Crisler, Christopher H. Herbert and others. The charter has been approved and the extension and addition to the present sanatorium plant will be undertaken promptly.

MISSOURI

Antituberculosis Campaign.—At a meeting of the St. Joseph-Buchanan County Medical Society, held April 22, plans were outlined for the organization of a society for the prevention of tuberculosis, and for the establishment of an outdoor ward at St. Joseph's Hospital for both city and county patients.

Sanatorium Officers.—The newly-elected board of managers of the Missouri State Sanatorium for Incipient Tuberculosis, Mount Vernon, at its meeting May 8, elected the following officers: President, Dr. William Porter, St. Louis; medical director, Dr. Edward W. Schaufli, Kansas City; vice-president, F. H. Miner, Aurora; secretary, W. L. Gupton, Montgomery City; auditor, W. T. Craig, Galena; superintendent,

Dr. Orville H. Brown (reelected), and assistant superintendent, Dr. George W. Orrick, Rolla.

State Society Meeting.—The opening address at the fifty-second annual meeting of the Missouri State Medical Association, held in Jefferson City, May 18-20, was delivered by Dr. J. N. McCormack, Bowling Green, Ky. The House of Delegates met and the general and medical sessions were held in the House of Representatives, and the surgical section met in the Senate Chamber. The following officers were elected: President, Dr. Tinsley Brown, Hamilton; vice-presidents, Drs. John M. Bell, St. Joseph; James A. Harris, Mount Vernon; Herbert C. Schobe, Paris; Bernard W. Hays, Jackson, and Jefferson L. Thorpe, Jefferson City; secretary, Dr. Andrew W. McAlester, Kansas City (re-elected); treasurer, Dr. J. Franklin Welch, Salisbury; delegates to the American Medical Association, Drs. Walter B. Dorsett and Edward J. Goodwin, St. Louis; orator in medicine, Dr. Nimrod P. Wood, Independence, and orator in surgery, Dr. Francis Reder, St. Louis. Hannibal was selected as the place of the next annual meeting.

MONTANA

State Tuberculosis League.—A meeting was held in Missoula, May 12, at which the Montana Antituberculosis League was organized with the following officers: President, Dr. William F. Cogswell, Livingston; vice-president, Mrs. T. J. Walsh, Helena; secretary, Dr. Thomas D. Tuttle, Helena; and treasurer, Dr. Mary B. Atwater, Helena.

State Board Election.—At the meeting of the State Board of Medical Examiners, held April 28, in Helena, the following officers were elected: President, Dr. Frederick M. Poindexter, Dillon; secretary, Dr. William C. Riddell, Helena, and treasurer, Dr. Sidney A. Cooney, Helena.—Dr. George B. Owen, Butte, has been appointed a member of the board.

State Medical Society Meeting.—At the thirty-first annual meeting of the Montana State Medical Association, held in Missoula, May 12 and 13, the following officers were elected: President, Dr. Thomas D. Tuttle, Helena; vice-presidents, Drs. John J. Buckley, Missoula; Frederick Cuttle, Hunter's Hot Springs, and Fritz E. Buchen, Hamilton; secretary, Dr. Herbert D. Kistler, Butte, and treasurer, Dr. Creswell T. Pigot, Butte. Hunter's Hot Springs was decided on as the next place of meeting.

Regulations for Car Sanitation.—Regulations have been issued by Dr. Thomas D. Tuttle, secretary of the State Board of Health, governing sanitation and ventilation of passenger cars in Montana. These regulations are the result of a conference between the State Board of Health, railway officials and state railroad commission. The rules provide that no person with a contagious or infectious disease shall enter a public conveyance except a hack, and then only after the person in charge of the hack has been notified. Train conductors are charged to notify health officers when they discover cases of contagious or infectious diseases on their trains, and the local health officer may, at his discretion, remove such persons from trains and hold them in quarantine until disinfecting. Spitting and throwing refuse on floors of cars is prohibited. Waiting rooms, smoking rooms and cars must be provided with cuspidors, and water for car tanks is not to be used without the approval of the board of health when a waterborne disease has developed in epidemic form in the municipality.

NEBRASKA

Personal.—The governor has appointed the following four secretaries for the State Board of Health in the so-called "defective act" of the last legislature: Dr. Archibald L. Muirhead, Omaha, two years; Dr. Clifford P. Fall, Beatrice, four years; Dr. Herschell B. Cummins, Seward, three years, and Dr. E. Arthur Carr, Lincoln, one year.—Dr. Malcolm Stewart has been appointed city physician of Tecumseh.—Dr. and Mrs. Lester M. Stearns, Kearney, sailed for Germany May 13.

State Tuberculosis Association.—At the annual meeting of the Nebraska Association for the Study and Prevention of Tuberculosis, held in Omaha, May 7, the following officers were elected: President, Dr. Harold Gifford, Omaha; vice-president, Dr. Francis A. Long, Madison; and executive committee, Mrs. K. R. Edholm, Omaha; Dr. Solon R. Towne, Omaha; Prof. H. B. Ward, Lincoln; Father Reusing, West Point; Mrs. Draper Smith, Omaha; Dr. Charles O. Giese, Holdrege, and Dr. Adrian F. Burkhard, Omaha.

Medical College Closes.—Dr. James F. Stevens, dean of the Nebraska College of Medicine, Lincoln, an affiliated school of the Nebraska Wesleyan University, in a letter to Dr. Ernest

J. C. Sward, secretary of the State Board of Health, notifies him that after careful consideration, the board of directors of the college has decided to close its doors to students and permanently retire from the field. The chief reason stated for the discontinuance was that Lincoln did not furnish the advantages which a college of medicine should have.

Graduation Exercises.—On May 20 the annual commencement exercises of the University of Nebraska, College of Medicine, Omaha, were held, when a class of nine was graduated and the annual address was delivered by Dr. William W. Keen, Philadelphia.—The seventeenth annual commencement of Creighton Medical College, Omaha, was held May 1, and a class of 29 was graduated. The degrees were conferred by the president, Eugene E. Magevney, and Dr. Archibald L. Muirhead, vice-dean of the school, delivered an address on "Thoroughness." At the annual banquet, Dr. Frank E. Coulter presided as toastmaster.

Organization of Hospital Staff.—The organization of the staff of the Douglas County Hospital, Omaha, has been effected by the county commissioner. The position of chief of staff has been done away with, and an executive council has been substituted, composed of Drs. Herschel P. Hamilton, Palmer Findley, and Frederick W. Lake. Dr. Wilson O. Bridges has been appointed consulting physician and the heads of departments are Dr. Paul G. Woolley, pathology; Dr. Solon R. Towne, hygiene and sanitation; Drs. Frederick W. Lake and Rudolph Rix, diseases of children; Dr. Palmer Findley, gynecology; Dr. Frank E. Coulter, mental and nervous diseases; Dr. Alonzo E. Mack, obstetrics; Dr. Frank S. Owen, diseases of the eye and ear; Dr. William F. Milroy, medicine, and Dr. Herschel P. Hamilton, surgery.

NEW HAMPSHIRE

State Society Election.—At the one hundred and eighteenth annual meeting of the New Hampshire Medical Society, held in Concord May 13 and 14, Dr. John B. Deaver, Philadelphia, delivered the oration on surgery, and Dr. Thomas M. Rotch, Boston, the address on medicine. The following officers were elected: President, Dr. Frank Blaisdell, Goffstown; vice-president, Dr. Alonzo S. Wallace, Nashua; councilors, Drs. Herbert K. Faulkner, Keen; Emery M. Fitch, Claremont, and Frederic Von Tobel, Lebanon; trustee, Dr. Silas M. Dinsmore, Keene; examiner, Dr. James T. Greeley, Nashua; delegate to the American Medical Association, Dr. Ferdinand A. Stillings, Concord, and alternate, Dr. William E. Reed, Nashua. At the annual banquet, Dr. Howard N. Kingsford, Hanover, officiated as toastmaster.

NEW YORK

To be Sued for Death of Physician.—It is announced that the city of Troy is to be called on to defend a suit for damages for \$150,000 for the death of Dr. Harry O. Fairweather, who died recently as the result of a fall from a ladder which broke while he was fighting a fire as a member of the volunteer fire department, the ground of suit being that death was brought about through the negligence of the city.

Bills Become Laws.—Governor Hughes has signed the Woods bill requiring death and birth certificates to be forwarded by local health boards to the State Bureau of Vital Statistics on or before the fifth day of each month. Under the present law no time is specified.—The Davis bill has also been signed prohibiting physicians who receive a salary from the state from taking fees for reporting tuberculosis cases.—The bill abolishing the Quarantine Commission and transferring its duties to Dr. Alvah H. Doty, health officer of the Port of New York, has been signed by the governor.

New York City

Personal.—Prof. Charles Baskerville, director of the chemical laboratory, College of the City of New York, sailed for London, May 15, to attend the Seventh International Congress of Applied Chemistry.—Dr. and Mrs. Frederick S. Dennis returned from Europe May 21.

Hospital Fund Distributed.—The distributing committee of the Hospital Saturday and Sunday Association appropriated \$72,000 of the funds received, the largest awards being made to the Montefiore Home and Hospital for Invalids and Mount Sinai Hospital, each of which received \$7,200.

Sea Air for Babies.—St. John's Guild has opened its sea-side hospital for babies at New Dorp, Staten Island, two weeks earlier than usual, the boats having already begun three daily trips. Under the policy of the guild the sick child secures admission for itself and mother and all children under the age of 6 in the family.

OKLAHOMA

Commencement.—A class of six was graduated from the College of Medicine of Epworth University, Oklahoma City, May 10. Chancellor George H. Bradford and Bishop W. A. Quayle delivered addresses to the class, and Dr. Arch A. West, dean of the school, presented the diplomas.

State Society Meeting.—The seventeenth annual meeting of the Oklahoma State Medical Association was held in Oklahoma City, May 11-13. The following officers were elected: President, Dr. Walter C. Bradford, Shawnee; vice-presidents, Drs. Charles L. Reeder, Tulsa; David A. Myers, Lawton, and John W. Duke, Guthrie; secretary-treasurer, Dr. Claude A. Thompson, Muskogee, and counselors: First District, Dr. J. Asa Walker, Shawnee; Second District, Dr. John W. Duke, Guthrie; Third District, Dr. Charles R. Hume, Anadarko; Fourth District, Dr. Adam B. Fair, Frederick; Fifth District, Dr. Frederick R. Sutton, Bartlesville; Sixth District, Dr. William G. Blake, Tahlequah; Seventh District, Dr. Ira W. Robertson, Dustin; and Eighth District, Dr. Herbert P. Wilson, Wynnewood. Tulsa was selected as the place of meeting for 1910.

PENNSYLVANIA

Inebriate Hospital Bill Vetoed.—The bill providing for the erection of a state hospital for inebriates, which carried with it an appropriation of \$100,000, was vetoed by the governor, who is said to have been really in favor of the measure, but was obliged to cut off all new institutions on account of the fact that the legislature had made appropriations of \$20,000,000 more than the income of the state.

Vital Statistics.—During March there were reported in the state 13,377 cases of communicable disease, chief among which were measles, 4,507; scarlet fever, 1,881; tuberculosis, 1,375; diphtheria, 1,283; chickenpox, 1,207; pneumonia, 943; whooping cough, 794; typhoid fever, 690, and mumps, 530. During February there were 10,230 deaths reported, of which 1,503 were due to pneumonia, 876 to tuberculosis, 528 to accidents, 516 to diseases of early infancy, 451 to nephritis, 352 to cancer, 198 to influenza, 161 to diphtheria, 136 to typhoid fever, 124 to scarlet fever, 111 to whooping cough, 82 to measles, and 68 to suicide.

Philadelphia

Free Bed for Jefferson Hospital.—In memory of her son, Dr. Charles N. Williams. Mrs. Sarah E. Williams, of Wellsboro, has endowed in perpetuity, a free bed in the Jefferson Hospital at an expense of \$5,000.

Personal.—Dr. R. Bruce Burns was stricken with apoplexy, May 19. He is reported to be convalescing in the Pennsylvania Hospital.—Drs. Eli L. Klopp and Dr. Augusta A. Koenig sailed for Europe May 22.

Failed to Register Births.—Five physicians and three midwives, who were arraigned, April 30, charged with failure to report births within ten days, as required, are said to have pleaded guilty and paid the cost of the proceedings.

Ex-Residents Meet.—The first meeting of the ex-residents association of St. Joseph's Hospital was held May 10. At the business meeting the following officers were elected: President, Dr. George M. Marshall; vice-president, Dr. John J. Moylan; secretary and treasurer, Dr. Joseph M. Spellissy, and historian, Dr. Joseph E. Roberts.

TENNESSEE

Endow Memorial Room.—Two families in Memphis and one family in Oxford, Miss., have endowed a memorial room in the new Baptist Memorial Hospital, Memphis, at a cost of \$1,000.

Alumni Election.—The Alumni Association of Memphis Hospital Medical College, at its annual election, April 29, elected Dr. Landon A. Yarbrough, Covington, president; Dr. R. E. Hering, Arlington, vice-president; Dr. Buford N. Dunavant, Memphis, secretary, and Dr. D. Max Henning, Memphis, treasurer.

Society Meetings.—At the semi-annual meeting of the Dickson County Medical Association, held in Dickson March 12, Dr. W. W. Walker was elected president; Dr. Joseph C. Flowers, vice-president; Dr. William S. Scott, secretary, and Dr. William J. Sugg, delegate to the state medical association, all of Dickson.—Claiborne County Medical Society was organized at Tazewell February 3, with Dr. Monte B. Carr as president, and Dr. Patterson as secretary.—The Nashville Academy of Medicine met April 6, and elected the following officers: Dr. Duncan Eve, Sr., president; Dr. James M. King, vice-president; Dr. Holland M. Tigert, secretary-treasurer; Drs. Matthew C. McGannon, William H. Witt and Mar-

vin M. Cullom, delegates to the state association, and Drs. Lucius E. Burch, Olin West and David R. Neil, alternates.

TEXAS

Health Board Organized.—The Board of Health of Austin has been organized with Dr. William J. Matthews, president; Dr. Thomas R. Pettway, vice-president; and Dr. Thomas S. Bennett, secretary.

Commencement.—The annual commencement exercises of the medical department of Fort Worth University were held May 4, when a class of 17 was graduated. The faculty address was made by Dr. Bacon Saunders, and the diplomas were awarded by the president.—The annual commencement exercises of the Baylor University, College of Medicine, Dallas, were held April 29, when a class of 16 received diplomas from the hand of President S. P. Brooks. The address of the evening was made by Dr. Garfield M. Hackler.—The sixth annual commencement exercises of the Southwestern University Medical College, Dallas, were held April 29, when a class of 9 was graduated. The degrees were conferred by R. S. Ilyer, president of the University, and the doctorate address was delivered by Bishop A. C. Garrett.

Legislative Work.—The legislature has passed a bill providing for the appropriation of \$40,000 for the establishment of a leper colony at some point in the state, at least five miles from any town, and making it a misdemeanor punishable by fine to conceal any case of leprosy.—An appropriation of \$90,000 has been made for the erection of a new building for the criminal insane at the Southwestern Insane Asylum, San Antonio, and an appropriation of \$35,000 for each of the state asylums for the care of the consumptive insane.—The tuberculosis commission bill was killed in the house May 3 by a vote of 59 to 35. The bill provided for the creation of a commission of three physicians experienced in dealing with tuberculosis, to be appointed by the governor, and to be furnished with \$5,000 for the gathering of information.

State Society Election.—At the forty-first annual meeting of the State Medical Association of Texas, held in Galveston, May 4-6, the following officers were elected: President, Dr. Witten B. Russ, San Antonio; vice-presidents, Drs. W. N. Wardlaw, Plainview; Charles M. Alexander, Coleman, and Joseph W. Largent, McKinney; counselors: First District, Dr. Felix P. Miller, El Paso; Fourth District, Dr. Stoyell E. Parsons, San Angelo; Eleventh District, Dr. Alfred L. Hathcock, Palestine; Thirteenth District, Dr. John H. Ball, Crystal Falls; and Fourteenth District, Dr. Frank D. Boyd, Fort Worth; trustee, Dr. John S. Lankford, San Antonio (re-elected); delegates to the American Medical Association, Drs. Edward H. Cary, Dallas; William M. Brumby, Austin, and Frank Paschal, San Antonio, and alternates, Drs. Ira C. Chase, Fort Worth; William R. Thompson, Fort Worth, and Hatch W. Cummings, Hearne. Dallas was selected as the next meeting place.

VERMONT

Tuberculosis Exhibit.—The State Tuberculosis Commission gave its exhibit in Rutland May 12 and 13. The exhibitions are being given in all the larger towns of the state, and in addition to the exhibit itself, illustrated lectures are delivered.

Personal.—Dr. Bertrand J. Andrews, Burlington, celebrated the twentieth anniversary of his appointment as superintendent of the Mary Fletcher Hospital recently.—Dr. Henry D. Chadwick, Pittsford, has been appointed superintendent of the new state tuberculosis hospital to be established at Westfield, Mass.—Dr. John D. Hanrahan, Rutland, celebrated the fortieth anniversary of his entrance into practice, April 12.—Dr. George C. Berkley, St. Albans, has resigned as surgeon of the First Infantry Vt. N. G.

WASHINGTON

Physician Sentenced.—Dr. Fred Peacock, Cathlamet, charged with manslaughter by causing the death of Madeline Longtine as the result of an alleged illegal operation, is said to have been sentenced, April 2, to serve an indeterminate sentence from one to twenty years in the state penitentiary. Motion for a new trial was denied. In February last the defendant was shot and dangerously wounded by the mother of the deceased girl.

Medical Inspection of Schools.—Dr. H. Eugene Allen, chief medical inspector of schools, Seattle, in a report of his inspection work for the first half of the fiscal year, shows that the medical inspectors made 885 school visits and examined 37,948 pupils, recommended treatment in 5,483 cases and excluded conditionally from school 1,211 pupils on account of

scabies, pediculosis and ringworm. There were also 392 cases of contagious disease unconditionally excluded from the schools.

GENERAL NEWS AND COMMENT

Consumptive Camp in Hawaii.—Funds have been contributed for a camp soon to be erected at Honolulu for the open-air treatment of tuberculosis.

Examination in Public Health Service.—A board of medical officers of the Public Health and Marine Hospital Service will convene in Washington on June 14, at 3 B St., S. E., at 10 a. m., to examine candidates for admission to the grade of assistant surgeon in the service. Candidates must be between 22 and 30 years of age, graduates of reputable medical colleges, and must furnish satisfactory testimonials. The examination will be physical, oral, written and clinical. Assistant surgeons receive a salary of \$1,600, and after four years' service are entitled to examination for promotion to the grade of passed assistant surgeon, with a salary of \$2,000 per year. Promotion to the grade of surgeon is made according to seniority, and after examination, and this grade pays a salary of \$2,500 a year. Officers are entitled to quarters for themselves and families, and all grades above that of assistant surgeon receive longevity pay. The tenure of office is permanent. For further information application should be made to the Surgeon General, Public Health and Marine Hospital Service, Washington, D. C.

Total \$4,639.65

Two thousand five hundred dollars is still necessary to raise this mortgage. There is information that at least \$500 of this amount has been subscribed and will be forwarded before the session of the American Medical Association. It would be gratifying to all concerned if it could be announced at the session that the entire amount had been raised. All subscriptions should be sent to Major M. W. Ireland, Medical Corps, U. S. Army, War Department, Washington, D. C.

Societies.—At the annual meeting of the Connecticut River Valley Medical Association, held in Bellows Falls, Vt., May 6, Dr. John D. Proctor, Keene, N. H., was elected president; Dr. Ansel S. Miller, Brattleboro, Vt., vice-president; Dr. James S. Hill, Bellows Falls, secretary, and Dr. Edward R. Campbell, Bellows Falls, treasurer. The Interstate Medical Club has been organized at Breckenridge, Minn., with the following officers: President, Dr. Timothy O'Brien, Wahpeton, N. D.; vice-president, Dr. Nathan F. Doleman, Tintah, Minn.; secretary, Dr. Clarence P. Rice, Breckenridge, Minn.; treasurer, Dr. Louis W. Armstrong, Breckenridge, Minn., and censors, Drs. Tobias Birnberg, Campbell, Minn.; A. Victor Young, Hankinson, N. D.; and Robert H. Devine, Wahpeton, N. D. The second annual meeting of the Tri-State Railway Surgeons' Association was held in New Orleans, May 3, when the following officers were elected: President, Dr. James J. Haralson, Forest, Miss.; vice-presidents, Drs. Henry F. Wilkins, Rayville, La., and J. Mosley Alford, Ellisville, Miss.; secretary, Dr. Joseph D. Martin, New Orleans, and treasurer, Dr. Robert W. Thompson, Lumberton, Miss. At the fifth annual meeting of the National Association for the Study and Prevention of Tuberculosis, held in Washington, May 13-15, more than 250 delegates from all sections of the country were present. The executive secretary reported that the association had gained 600 members during the year, and that 34 out of 40 state legislatures had considered legislation on tuberculosis. At the meeting of the advisory council Dr. Victor C. Vaughan, Ann Arbor, Mich., delivered an address on "Tuberculosis Legislation in Municipal and State Governments." Dr. Henry M. Braeken, Minneapolis, Minn., was elected president

of the section. Great interest attached to the address of Dr. Homer Folks, New York, on recent tuberculosis campaigns and their results. In his opinion, the control of tuberculosis is a problem for local authorities, and he believes the most effective work that can be done by local organizations is to follow the example of the national association in forming local organizations and committees to take the responsibility of securing county and municipal control of the disease. Drs. William Osler, Oxford, England, and William M. Welch, Philadelphia, spoke of the results of the work on tuberculosis, and Speaker Cannon and Ambassador Brice gave their views regarding the outlook. Nathan Strauss, in his address, stated that he had discovered that one out of every eighteen samples of milk sold in Washington was tuberculous, and that one out of every ten dairies in the city supplied tuberculous milk despite the recent vigorous campaigns and that efforts had thus far failed to check the ravages of the disease.

CANADA

Memorial Chair.—At the recent convocation of McGill University, it was announced that \$60,000 had been guaranteed by the committee to establish a chair of chemistry in memory of the late Professor Harrington.

Hospital Notes.—Montreal is about to have a hospital to be devoted entirely to the care of advanced cases of tuberculosis. Grace and Western hospitals, Toronto, are to be amalgamated in a short time. A new Western Hospital is to be erected soon, to cost \$150,000.

Graduation Exercises.—At the annual convocation of the Western University Medical Department, London, a class of 23 was graduated. Dr. Hadley Williams delivered the faculty address, and Rev. E. B. Lancely was the orator of the occasion. At the twenty-sixth annual graduation exercises of Manitoba Medical College, Winnipeg, May 13, Dr. Robert S. Thornton, member of the Provincial Parliament from Deloraine, delivered the principal address, and a class of 36 was graduated.

Tuberculosis in Prince Edward Island.—It is reported that out of the 950 deaths which occurred in Prince Edward Island during the year ended May 31, 1908, 142 were due to tuberculosis. The society for the prevention of tuberculosis in that island has recently been rejuvenated and medical men have been appointed to the chief offices therein. Lectures are being given and a dispensary has been established in Charlottetown. An appropriation of \$600 has been made by the provincial parliament for the work against tuberculosis.

Personal.—Dr. Dyer, Vancouver, B. C., has been appointed assistant to the medical health officer. Dr. Albert K. Pyne, Toronto, has been appointed chairman of the local milk commission. Drs. Geoffrey Boyd and Charles Trow, Toronto, have gone to Europe. Dr. George A. Armstrong, Montreal, has returned from Paris. Dr. Robichaud, Montreal, has resigned as superintendent of the Hôtel Dieu, Montreal, and has been succeeded by Dr. G. H. Baril. Dr. H. H. McIntosh, Vancouver, B. C., has resigned as superintendent of the Vancouver General Hospital, and has been succeeded by Dr. White-law. Dr. James Sampson, Windsor, Ont., has been appointed chief lecturer on "Old Age Pensions" by the Dominion government. Dr. William I. Senkler, Vancouver, is reported to be critically ill in St. Vincent's Hospital, Portland, Ore. Dr. James Christie, on May 1, celebrated the fiftieth anniversary of his entry into practice in St. John, N. B. Dr. J. B. Leathes, F.R.S.C., London, has been appointed professor of chemical pathology in the faculty of medicine of the University of Toronto.

FOREIGN

Psychologic Congress.—The sixth International Congress of Psychology will convene at Geneva, Switzerland, August 3-7, under the presidency of Prof. Thomas Flournoy. The general topics for discussion are "Feelings," "Subconsciousness," "Measure of Attention," and "Religious Psychology." The special topics are the "Psychopedagogical Classification of Backward Pupils," "Pedagogical Psychology," "Orientation at a Distance," and "Perception of Position and Movement of the Body and Limbs." Under standardization will be included terminology, standard colors, enumeration of errors in testimony experiments, notation of age of children and mathematical determination of numerical results of experiments.

Recent Deaths in the Profession Abroad.—In addition to the deaths of members of the profession mentioned by our foreign correspondents, we record those of E. Galvagni, professor of clinical medicine at Modena since 1880, a leader in the profession in Italy, and author of important works on peritonitis,

polyserositis and other phases of internal medicine; E. Kufferath, professor of obstetrics at Brussels; J. R. Costa, professor of medical physics at Buenos Aires; E. R. Haug, professor of otology at Munich; A. Almaraz, professor of chemistry at Mexico; P. de A. Magalhaes, professor of surgical pathology at Rio de Janeiro and author of numerous works on liver and cardiovascular affections, neuritis and beriberi.

British Medical Association.—The seventy-seventh annual meeting of the British Medical Association will be held in Belfast, Ireland, July 23 to 31, 1909. The scientific portion of the meeting will begin with the president's address, on Tuesday, July 27, and the sections will meet on the three following days. Saturday, the 31st, will, as usual, be reserved for excursions. The address in medicine will be delivered by Dr. R. W. Philip, physician to the Royal Infirmary and Royal Victoria Consumption Hospital, Edinburgh; that in surgery by Mr. A. E. J. Barker, professor of surgery, University College, London; and that in obstetrics, by Sir John W. Byers, professor in midwifery and diseases of women, Queen's College, Belfast. The "Popular Lecture," which of late years has become a feature and consists of a lecture open to the public at large, on some subject of general interest and welfare, will be delivered by Dr. A. J. Macdonald. In the Section on Hematology and Vaccine Therapy, presided over by Sir Almaroth Wright, there will be papers on "Typhoid-Carriers" (Dr. Houston); "The Bacteriology of Cystitis" (Captain Douglas); and "The Bacteriology and Vaccine Treatment of Acne" (Dr. Fleming). A discussion on "The Early Diagnosis of Tuberculosis" will be opened on July 29 by Professor Calmette of Lille. In the Section on Hygiene and Public Health, compulsory notification of all forms of tuberculosis, latent infections of the diphtheria bacillus, and sewage discharge into tidal waters will be among the subjects. The discussion on latent infections of the diphtheria bacillus will be jointly with the Laryngologic Section. In the Section on Medicine, metabolism, the medical aspects of athleticism, and adolescent albuminuria or mucous colitis will be discussed. In the Navy, Army and Ambulance Section, the following subjects are proposed:

1. Effect on Health of Service in Submarine Boats;
2. Conditions of Life on Boys' Training Establishments on Shore;
3. Medical Arrangements for War in Ship;
4. A Detailed Scheme for an Unexpedient Material Available on Board Ship;
5. Medical Officer;
6. Probable Effects in Treatment of Syphilis by Means of Organic Arsenical Compounds;
7. The Importance of the Permanent Attachment of Ample Transport under the Command of the Medical Officer to each Field Medical Unit;
8. The Infective Pneumonias, their Incidence, Causes, Prevention, and Treatment during Organization of the Home Ambulance Orth its Amplification and ing Suggestions for Research on the Work of Medical Officers of Recent Research;
9. Diagnosis and Treatment of Pulmonary Tuberculosis in the Service;
10. Collection and Disposal of Wounded in War.

"The Graver Forms of Puerperal Sepsis and Endometritis" will occupy the attention of the Section on Obstetrics and Gynecology, and "Eye Injuries in Relation to the Workman's Compensation Act," "Vascular Diseases of the Retina," and "Diseases of the Lymphoid Tissues of the Conjunctiva" (Mr. Treacher Collins, F.R.C.S.) that of the Section on Ophthalmology. The Section on Pharmacology and Therapeutics will discuss spinal anesthesia and the treatment of edema. In the Section on Psychological Medicine, the subject of "Somatic Delusions and Local Lesions" will be opened by Dr. C. A. Mercier. The Section on Tropical Medicine will discuss, on July 28, "Persistence of the Tropical Diseases of Man Due to Protozoa" (C. W. Daniels, M.D.); July 29, "Treatment of Chronic Recurrent Dysentery with Special Reference to the Possibilities of Surgical Treatment" (Mr. J. Cantlie, F.R.C.S.); July 30, "Feeding and Treatment of Children in the Tropics" (Dr. W. Carnegie Brown). The annual dinner will take place on July 29, and the reception on July 30. The recreations, which are always an important feature with the British Medical Association, will include a golf competition, a cricket match, and in all probability, the launch of one of the great steamships for which the Belfast shipyards are famous.

LONDON LETTER

(From Our Regular Correspondent)

LONDON, May 15, 1909.

Bill to Regulate the Use of Anesthetics

As shown in previous letters, the large and increasing number of deaths which occur under anesthesia has aroused considerable public attention and a bill is now under consideration in parliament to regulate their administration. It is to be a penal offense for any person not medically qualified to administer a drug for the purpose of producing a state of

unconsciousness during any medical or surgical operation or during childbirth. For the first offense the maximum penalty is \$50 and for the second \$100. Two exemptions are allowed. An anesthetic may be administered under the immediate direction and supervision of a legally qualified practitioner or in the event of the person administering it having reasonable grounds for believing that the delay caused by calling in a physician would endanger life. The bill is not to apply to those already registered under the Dentists Acts. It will be a severe blow to the numerous unqualified dentists who practice, though they are largely the product of circumstances. Registration of dentists was instituted in 1878. Before this date any one could practice dentistry. The supply of dentists with a qualification of a medical college was then small and all persons who were then engaged in the practice of dentistry were admitted to the register. After that period only qualified dentists were admitted to the register, but the supply has never equalled the demand for dentists. Consequently there is a large body of unqualified practitioners throughout the country. Until recently they were not in any way interfered with as long as they did not adopt the title "dentist," which is reserved for registered practitioners. This did not place them at much disadvantage, as they adopted such equivalent designations as "tooth specialist," "dental institution," etc. But recently the law has been set in motion against them and the courts have decided that the use of such designations is illegal, as they imply that the person using them is a dentist. Even the exhibition of sets of teeth in the window or the notice "teeth skilfully extracted" are now penal. Under the bill these practitioners will not only be prohibited from administering an anesthetic, but no physician may administer one for them.

Discomfiture of the Antivaccinationists

Mr. Lupton, M. P., the leader of the antivaccinationists in the House of Commons and a truculent advocate of this fallacy, asked a question in the House which received an unexpected answer. He inquired whether during the late outbreak of smallpox in Bristol the many unvaccinated children in the city showed any special liability to the disease. The president of the local government board, Mr. Burns, replied that any comparison between vaccinated and unvaccinated children should be made in respect to those children who were exposed to infection. At Bristol the persons who suffered from smallpox or were in contact with them were so carefully supervised that few unvaccinated children were so exposed. Of the children under the age of 14 so exposed 9 were attacked by the disease. Two of these had been vaccinated and in them the attacks were abortive. The remaining 7 children were unvaccinated, except that 2 were vaccinated during the incubation period of the disease. Of the 7 unvaccinated children 3 died, all of whom suffered from confluent smallpox.

Malaria in British Colonies

Major Ross, the discoverer of the malarial parasite, delivered a lecture on "The Campaign Against Malaria" before a distinguished audience, including Lord Rayleigh, Sir William Crookes, Sir James Dewar, Professor Arrhenius, and others at the Royal Institution. He pointed out that in Italy by distribution of quinin and mechanical protection against mosquito bites the number of deaths from malaria had been reduced from 21,033 in 1887 to 4,160 in 1907. At Ismalia, as the result of the methods which he had advised for the reduction of mosquitoes the disease had ceased to be endemic since 1904. Work at Klang and Port Sweetenham in the Malay States had been equally successful. Excellent campaigns against the disease had also been conducted at Durban, Hong Kong, Khar-tum, Candia, and Port Said. But in India he could find no evidence of a generalized effort against the disease. In 1907 statements were published of what had been done in 21 colonies. Only in 7—Southern Rhodesia, Papua, Mauritius, British Central Africa, Gambia, Ceylon, Southern Nigeria—was there evidence of any real interest in the matter. The reports from the Bahamas, Barbadoes, Jamaica and St. Kitts-Nevis showed nothing but neglect of public duty. The immediate responsibility for the neglect lay with the heads of the sanitary services of the colonies. Though many capable individuals were to be found in those services colonial governments, as a rule, were too careless in selecting the men to whom they entrusted the public health.

London School of Tropical Medicine

The London School of Tropical Medicine has started an advanced course in medical zoology which includes protozoology.

arthropodology and helminthology. Arrangements have been made so that the course in all three subjects can be taken during three months or the whole time may be spent on one subject. Only students who have attended the ordinary course or those who can satisfy the teachers that they possess sufficient rudimentary knowledge are eligible. Special arrangements may be made for teachers who desire to devote themselves to any particular branch or to undertake research work.

State Registration of Nurses

An influential deputation which was recently received by the prime minister urged that facilities should be given by the government for the introduction of a bill establishing a statutory council for the examination of trained nurses. Sir Victor Horsley spoke on behalf of the British Medical Association and said that the medical profession desired to see the nursing profession properly equipped. The premier pointed out, however, that there was considerable opposition to the proposal. He had the views of persons who were entitled to the highest consideration who were altogether opposed to the proposed legislation. These included many of the chairmen of the London and provincial hospitals. He had also received a list of names of 100 members of the medical profession in London, including some of the most eminent, particularly in the department of obstetrics and surgery and a list of 120 names in the provinces who were entirely opposed to the proposal. So also were 49 matrons of the London hospitals and 109 matrons of the provincial hospitals. If such registration was enacted it would not in the least prevent persons who had not satisfied the examiners from pursuing the profession of nursing. Those outside the pale could carry on their profession as before. Under the circumstances he did not think the deputation could expect him to do more than promise to give the most careful consideration to their arguments.

PARIS LETTER

(From Our Regular Correspondent)

PARIS, April 29, 1909.

Commercial Medical Societies

The *Association Générale de prévoyance et de secours mutuels des Médecins de France* celebrated in April its semi centennial, as described in my letter on page 1592. At the general assembly the following day a question of professional ethics was raised which has occupied professional attention for a long time, but has not hitherto dared to show itself openly.

There exist in France certain medical societies claiming to be provident societies, which, in reality, are only commercial societies, and tend to deprive physicians who have subscribed to their statutes of liberty of conscience. The chief of these societies is the *Prévoyance médicale*, which is a purely commercial association, consisting of physicians and some pharmacists who possess either stock in mineral waters, or mineral springs themselves, and who undertake to recommend them in preference to other similar waters. Moreover, the physicians who belong to these societies are induced to prescribe soaps, medicated baths, meat preparations, etc., and even pharmaceutical products, such as the "grains de Vals." Officially, the society professes to leave its members entire liberty, not requiring them to prescribe its products save when the proper indication presents itself. But, as a matter of fact, those who prescribe them little are not long in being called to order, and the representative of the society does not hesitate to say to them "when an indication for prescribing our product fails to present itself you must know how to make one." In return the society assures to its members the following advantages:

Every member holds one or more shares in the society, which distributes an annual dividend, naturally varying according to the success of the sales of the society's products. Moreover, the society promises to all its adherents, at 60 years of age, a retiring pension, which at present amounts to 1,000 francs; their widows are also pensioned, and their orphans supported till they become of age. Quite recently the Provident Medical Society has organized a fund for indemnity in cases of sickness; for this the members have no contributions to pay, but must prescribe alimentary products, farinaceous foods, and other dietetic products. It is hardly ten years since the opinion of the entire medical body was almost unanimous for rejecting the principle of such an association. There were only certain physicians, very few in number, who were affiliated to this society, which at that time called itself the Society of Mineral Waters; and in 1900, when the question was put to the Congress of Deontology and Professional Medicine, Dr. Poirson, president of the Union of Medical Syn-

dicates, declared—without calling forth any protest—that the Provident Medical Society was one of those commercial affairs from which the physician ought to keep himself aloof. Unfortunately, since then too large a number of physicians have changed opinions on this question, either because of the increasing difficulty encountered in living by the normal practice of their profession, or because they have not sufficiently reflected on the gravity of the consequences for the medical body that the spread of such concerns must have—consequences grave, not only from a material point of view, for in proportion as these practices should become known to the public, the latter will less and less seek professional advice, which they know not to be disinterested; but still more, from a moral viewpoint, because such practices will end in the physician being regarded simply as an ordinary tradesman.

The local society of the department of Landes is disturbed at this state of things, which tends to discredit the entire medical body "by making of the physician a peddler in specialties." It consequently appealed to the board of the *Association Générale* mentioned above, presenting a resolution calling on the association to point out to all its members and to all the physicians of France, the moral danger that the medical body runs in entering on the path of so-called provident medical, but really commercial, societies. In conformity with the statutes, the board of officers has had to express its opinion on this resolution. It has done so very courageously through its general secretary, Dr. Lepage, who in his report has asked that the resolution of the Society of Landes be taken into consideration, that is to say, be referred for examination to the local societies, to be then discussed at the general assembly in 1910. A group of physicians, however, demanded: (1) That the resolution of the Society of Landes be erased from the orders of the day, and consequently that it should not be discussed; (2) that in the report of the general secretary everything relative to this question should be suppressed, and that this part should be neither read in session nor printed in the bulletin of the association. This maneuver of the partisans of the *Prévoyance médicale* society failed completely, and indeed resulted in the immediate opening of a discussion on the question. On the observation of one delegate, that everyone under the circumstances ought openly to take his responsibility, it was decided that the vote should be public and by name, each delegate answering to his name with Yes or No. This is the first time that a general assembly of the association has voted in this fashion. The vote resulted as follows: For taking under consideration the resolution of the Society of Landes, 113; against, 17. The resolution is therefore referred for the consideration of local societies, and without prejudging the view that these societies will take, we may congratulate ourselves that the general assembly should have taken a decision so conformable to the honor and dignity of the medical profession.

On the other hand, it is interesting to note that the council of the association of pharmacists complains equally of the existence of these so-called provident medical societies based on the exploitation of mineral waters and various other products. Recently, the council of the Union of Medical Syndicates has been overwhelmed with various propositions on this subject. Unfortunately, under the pretext of respecting the independence of the physician, the council has passed an order of the day which opens wide the door to all kinds of abuses and to commercial alliances between certain unscrupulous physicians and pharmacists. The administrative council of the Union of Medical Syndicates of France, holding that the physician ought to preserve absolute liberty of prescribing in regard to the patient, and to be dependent on nothing except his own conscience, denies to all professional bodies, medical or other, the right to dictate to him his conduct in this matter.

BERLIN LETTER

(From Our Regular Correspondent)

BERLIN, May 6, 1909.

The New Imperial Insurance Bill

This bill, which I have mentioned in a previous letter, is creating a considerable interest among the classes affected. The pharmacists seem to be well satisfied, but all the other trades or professions make more or less criticism. On the part of the medical profession one can take many exceptions to the bill, and in most publications the proposed law is designated as unacceptable to the medical men. The business committee of the German Medical Association (*Deutscher Aerzte Vereinsbundes*) proposes some amendments which will be put before medical councils and societies for discussion.

The principal debate on the part of physicians will take place at the meeting of the German Medical Association (Aerztetag) which meets at Lübeck in June.

Personals

Prof. George Klemperer, for many years an assistant of v. Leyden, has been chosen director of the department of the city hospital, Moabit, as successor of the late v. Renvers. This choice not only corresponds to the expectations of the initiated, but is fully justified by the scientific qualities of Klemperer. Klemperer has been for some years in charge of the second medical division of the same hospital, so that his promotion to a higher position is quite in order.

Professor Stern of Breslau, the superintendent of the university policlinic in medicine at that place, has accepted the call as director of the medical clinic at Greifswald in place of Minkowski. Stern has secured his reputation by the preparation of a very widely used text-book on the connection between trauma and internal diseases.

Professor Heine of Königsberg has accepted the call as director of the clinic and policlinic for ear diseases at Munich as successor of the lately deceased Professors Bezold and Haug. In this case the disputed question which I have lately referred to, regarding the combination of instruction in laryngology and otology, has been settled for Munich by retaining the previous status of separate instructors for the two specialties.

On May 3 Professor Guttstadt died at Berlin, aged 69. Guttstadt was a member of the Prussian National Statistical Office and had rendered very good service in the field of medical statistics and public hygiene by a series of excellent investigations.

April 20, Professor Laqueur, formerly director of the Strassburg eye clinic, died at the age of 69. He was at one time an assistant of v. Gräfe and later of Professor Liebreich of Paris, but was professor of ophthalmology at Strassburg, 1872 to 1907.

The interregnum at the medical clinic at Bonn, which has lasted for nearly a year, is finally terminated. The direction of the policlinic, which was rendered vacant when Professor Leo was appointed as successor of Professor Binz, has been assumed by Professor Krause, the director of the medical policlinic of Jena. The successor of v. Krause is Professor Lommel.

Private Hospital for Middle Class Patients

The question, still unsettled for Berlin, whether beds shall be provided in city hospitals for middle class patients, has received a temporary solution in our neighboring city, Charlottenburg, by the establishment of a clinic with 50 beds for middle class patients in the Central Charities building (Zentral-Wohlfahrts-Gebäude), erected and dedicated a few days ago by the Women's Patriotic Association of Charlottenburg (Vaterländischen Frauenverein Charlottenburg). The daily price for a bed is 6 to 10 marks (\$1.50 to \$2.50). The building is further notable as furnishing a central bureau for the charitable work of the city of Charlottenburg. The house contains rooms for the care of pulmonary patients, a diet kitchen with special rooms for the feeding of school children, a room for the care of infants, the central bureau of the workingmen's recreation parks, a place for the care of alcoholic patients and an intelligence office for summer outings for people of moderate means and some other society bureaus. There is no doubt that such a centralization of charitable work in many respects will be very advantageous. The business between the individual charitable societies is facilitated and accelerated, time and labor are spared, and an equitable distribution of assistance is assured.

VIENNA LETTER

(From Our Regular Correspondent)

VIENNA, May 8, 1909.

Health Statistics for Austria

A government report for 1907 contains some very instructive figures. According to this there were altogether 26,000,000 inhabitants in Austria (without Hungary); 731 hospitals, with 52,870 beds were available for patients; compared with 1906, this means an increase of 17 hospitals and 1,350 beds. The number of in-patients occupying these hospitals was 615,125, an increase of 22,600 against 1906. The proportion between population and hospital beds varied very much. Thus in Vienna there was one bed for each 269 persons, in Trieste one for each 112 inhabitants, in Galicia one for 1,208 only. The most important affections treated in the hospitals were: injuries, 96,616; ophthalmic cases, 37,125; venereal diseases,

including syphilis, 39,740; tuberculosis, 31,845; bronchial catarrhs, 27,046; diseases of female sexual organs, 25,223; rheumatic affections, 22,868; diseases of stomach, not malignant, 19,142; heart disease, 13,948; cases of malignant tumors, 12,860; diseases of the bones, 12,081; cases of pneumonia, 11,512. There were 69 cases of smallpox with three deaths in this year, and one fatal case of Asiatic cholera.

Of course these figures comprise only the cases admitted into hospitals. In order to indicate the actual numbers of cases of disease, it must be stated that only 11 7/9 per cent. of all tuberculous persons who died that year died in hospitals. There were 96,000 deaths from this cause alone in the empire.

There were 32 public and 9 private lunatic asylums with 29,860 patients: of these 3,646 suffered from acquired idiocy, 2,712 from paranoia, 2,286 from general paralysis of the insane, 1,748 from alcoholic mania, 1,524 from epileptic insanity, 1,180 from congenital insanity, 500 from congenital idiocy. Of each 100 insane persons only 51 per cent. were in asylums, 70 per cent. in infirmaries, and 39 per cent. in private care. In 18 maternities with 1,917 beds, there were 29,681 mothers with 20,969 children; furthermore, there were 8 foundling asylums with 731 cots and 556 beds for wet-nurses. In these institutions 41,098 children were born. In 22 institutions for deaf-mutes, 1,938 persons were cared for while 27,500 were cared for privately. In 15 institutions for the blind 1,159 inmates were counted against 12,890 cared for privately. This year 767,950 persons were vaccinated for the first time. There were 263 *Curorte* or health resorts with nearly 500,000 health-seekers. Carlsbad with 60,000 visitors heads the list. There were 70 *Curorte* with 20,000 to 30,000 visitors paying the health tax (*Curaxe*) and 62 with 10,000 to 20,000 visitors. The remainder are smaller health resorts.

It is interesting to note that 65 per cent. of all medical men held public appointments, of whom more than 30 per cent. had to rely on their income only, as they had to give all their time to their appointments while the other 70 per cent. of this class of physicians were allowed to follow private practice as well. The number of appointments is increasing constantly; so that in a few years to come every physician in this country will hold some position paid for by the community. This will be the case especially when the new bill for *Sozialversicherung* (compulsory insurance of wage-earners) becomes law. Out of all practitioners 95 per cent. are doctors of medicine; 5 per cent. are masters of surgery or masters of obstetrics only, and this latter degree is no longer granted; all graduates must go in for the M.D. diploma. The number of practitioners has lately been increasing even more slowly than the population, but still the proportion is one doctor for each 2,200 of the population. As there were 12,260 practitioners in the country, naturally the towns are better off, having one doctor for each 900 to 1,200 inhabitants, while the country has a proportion of 1 to 2,600 and 1 to 5,600. As regards the income trustworthy information is of course hardly obtainable, but the values of appointments are known. The highest salary is \$2,600 a year with certain emoluments, amounting to about 30 per cent., the lowest \$300. Only 6 per cent. of the salaries reach the upper limit; 22 per cent. are at the bottom; the majority have \$600 to \$1,500 a year with the above-mentioned income.

Pharmacology

AGAIN LLOYD'S "CONSUMPTION CURE"

The "Discoverer" Is Awarded a Diploma of Merit by a Learned (?) Society

On two occasions we have given space to a "consumption cure" fake known at various stages of its career as "Lloyd's Specific," "Sol. Anti-Phthisis (Lloyd)," "Aiesol," and finally "Re-Stor-All," the promoter being one Judd Q. Lloyd of St. Louis. Under the first three names it was advertised as an "ethical" remedy; the last name was given it when a company was organized by its promoter to place it on the market as a "patent medicine." This, at least, was the avowed intention. We find, however, in the daily papers that the nostrum is advertised not under its "patent medicine" name, "Re-Stor-All," but under its "ethical" name, "Aiesol." One adver-

tisement which starts out with what is alleged to be a testimonial from a physician, contains in addition the following statement:

"On Dec. 15, 1908, the London Society of Science, Letters and Art, of London, England, which was established in 1881 for the purpose of determining the highest scientific and literary achievements of each year, awarded a diploma of merit to Judd Q. Lloyd in recognition of his valuable services to mankind in discovering 'Alesol,' the only successful treatment for consumption, and was elected an honorary member of that well-known society. Only one such diploma is issued each year in any country."

It seemed strange that a "well-known society" should award a "diploma of merit" to Judd Q. Lloyd for having "discovered" a fake consumption cure and especially that this "society" should rank the "discovery" as the "highest scientific and literary achievement" in the United States for that year. We tried to find out, therefore, something about the society, but were unable to get any trace of it in the various lists of scientific organizations in London. To obtain light on the subject, the editor of *London Truth*, who has shown up so many fake "societies," was written to. He replied as follows:

"The Society of Science, Letters and Art, of London, is a swindle to which at one time we devoted a great deal of attention, and it figured for a time in the *Truth* 'Cautionary List,' but it has lapsed into obscurity in recent years, and we have not referred to it for some time. The concern was started by a man named Albert Sturman who at one time kept a private school for boys in London and also acted as an agent for the sale of various bogus degrees produced on your side of the Atlantic. He then started a degree factory of his own under the above title. He took a house in Kensington and got together a serio-comic literary society, the members of which were entitled to attend *conversaciones*, concerts, etc., in his front parlor, and to dub themselves 'F.S.Sc. (Lond.)' if they paid the fellows' subscription. He also sold them hoods and gowns, specially designed for the benefit of church organists, and generally practiced all the tricks of the trade. He also did very good business by instituting a system of examining small private schools in the provinces and giving the pupils certificates. As he styled his examinations the "Kensington Locals"—which suggested that they were in some way connected with the Government Science and Art Department at South Kensington—country schoolmasters and schoolmistresses patronized these examinations extensively; and I need not tell you that Sturman gave them good value for their money by always passing a fair proportion of pupils."

"In an evil moment for himself, Sturman, who was a stupid and illiterate man, came here to see us, and we published the interview, which made very funny reading. After this the concern went down hill and Sturman himself died six or seven years ago. His wife, however, who was really the active partner in the business, carried it on afterward with some success, but, as I have said, it has dropped out of sight recently, though one occasionally comes across people who display the 'F.S.Sc. (Lond.)'."

Nostrums Containing Habit-Forming Drugs

We recently referred to the large amount of information of interest to physicians which appears in the "Report of the President's Homes Commission," and we quoted from the report a list of "patent medicines" which contained practically no medicinal agents except alcohol. In another part of the same report, Dr. Lyman F. Kebler, chief of division of drugs of U. S. Department of Agriculture, says: "There are on the market many medicinal preparations which contain as ingredients habit-forming drugs. Such drugs are: Alcohol; opium and its derivatives, notably morphin, codein and heroin; cocain; chloral; cannabis indica; acetanilid; etc." Some of these preparations containing habit-forming drugs other than alcohol are given in the "President's Homes Commission" report and are here arranged alphabetically under the habit-forming drug which they contain:

CANNABIS INDICA	
One Day Cough Cure (also morphin)	Piso's Cure
CHLORAL	
Capitol	D. D. D. Remedy
COCAIN	
Agnew's Powder	Coco-Bola
Anglo-American Catarrh Powder	Tucker's Asthma Cure

OPIMUM AND ITS DERIVATIVES

Boscher's German Syrup (morphin)	Harrison's Opium Elixir (opium)
Brou's Injection (morphin)	Hooper's Anodyne, The Infant's Friend (morphin)
Carney Common Sense Cure (morphin)	Jayne's Expectorant (opium)
Children's Comfort (morphin)	Maguire's Compound Extract Benne (morphin)
Colwell's Egyptian Oil (opium)	Mexican Oil (opium)
Crossman's Specific Mixture (opium)	Mrs. Winslow's Soothing Syrup (morphin)
Dr. Drake's German Croup Remedy (opium)	One Day Cough Cure (morphin, also cannabis indica)
Dr. Fahrney's Teething Syrup (morphin)	Petit's Eye Salve (morphin)
Dr. James' Soothing Syrup (heroin)	Pierce's Smart Weed (opium)
Dr. Seth Arnold's Cough Killer (morphin)	Rexal Cholera Cure (opium)
Dr. Moffett's Teethina; Teething Powders (opium)	Shiloh's Cure (heroin)
Fruit-Lax (morphin)	Taylor's Sweet Gum and Mullein Compound (morphin)
Godfrey's Cordial (opium)	Tousley's Sneezelless Snuff (morphin)
Gowan's Pneumonia Cure (opium)	Tubercine (opium)
Habitina (morphin)	Victor Lung Syrup (opium)
	Watkin's Anodyne (heroin)
	Wright's Instant Relief (opium)

Association News

THE ATLANTIC CITY SESSION

Additional Announcements—Alumni Reunions—Meeting Places—Other Information

RAILROAD RATES

The Committee on Transportation and Place of Session announces the following rates to the Atlantic City Session. In the New England, Trunk Line, Central and Western passenger associations territories, a rate of one and one-half fare, based on fares in effect April 1, 1909. In the trans-Missouri territory, which includes the Dakotas, Nebraska, Kansas, and the eastern half of Colorado, double the one way fares to Missouri River stations, added to rate of fare and one-half for the round trip tendered therefrom (not to exceed otherwise summer tourists' selling fare to the eastern gateways of this association where same are in effect, added to fares tendered by the Central Passenger Association). From the trans-continental territory, which includes the states west of Colorado, special rates have been made up to the trans-Missouri territory above mentioned. A special rate of \$26.00 has been made for the round trip from Chicago to Atlantic City. This is less than the rate of the fare and one-half, and all those who pass through Chicago or St. Louis may therefore avail themselves of this rate from Chicago or St. Louis. A return limit of 30 days is placed on the \$26.00 rate from Chicago, and stopovers may be made at Baltimore, Washington and Philadelphia providing the ticket agent is so informed when tickets are purchased. A special rate of \$28.20 has been made from Chicago to New York and return for those who wish to go to New York City. Those who wish to make this trip may stop over at Philadelphia by depositing their tickets at Philadelphia and then may go on to Atlantic City to attend the session, taking up the tickets on return to Philadelphia and continuing the trip to New York. The rates here given are for the first-class standard roads and are good on all trains except the 20th Century Limited and the Pennsylvania Special. The rate from Chicago by the differential roads is \$25.70 in place of \$26.00 by the standard, and to New York is \$25.50 instead of \$28.20, but the purchaser should remember that he is obliged to go and return by the same route. Up to the present time we have been unable to secure any special rates from the Southeastern Passenger Association. In all cases, before purchasing tickets, consult the local ticket agent and get all particulars in regard to the special rates from that particular point.

M. L. HARRIS, Chairman.

OTHER ALUMNI REUNIONS

A partial list of the entertainments to be given to the visitors at the Sixtieth Annual Session of the American Medical Association in Atlantic City, June 8-11, was published in *THE JOURNAL* May 15, page 1594. The following additional alumni reunions are announced for Tuesday, June 8:

7:30 p. m.—Harvard University alumni meeting and dinner at Hotel Windsor
9 p. m.—Dartmouth Medical College alumni reunion at Hotel Chelsea
9 p. m.—Jefferson Medical College alumni reunion and smoker at Hotel Royal Palace.
8:30 p. m.—Medico-Chirurgical College of Philadelphia alumni reunion and smoker at Hotel Rudolf
8 p. m.—Vanderbilt University Medical Department alumni banquet at Young's Hotel

Other alumni reunions are to be held this same evening for medical departments of the University of Vermont and the University of Minnesota and for Long Island Medical College and Tufts' Medical School.

"Wiener Studenten" will hold a reunion, supper and smoker at Old Vienna, Wednesday, June 9, at 6:30 p. m.

The University of Pennsylvania Medical Department alumni will have lounging, smoking and writing rooms at Young's Hotel the entire week; Vanderbilt medical alumni will also have their headquarters at Young's Hotel.

HOTEL HEADQUARTERS

A large list of hotels with an elaborately tabulated schedule of rates and accommodations, and also with a map of Atlantic City showing the locations of the hotels, appeared in THE JOURNAL, May 1, page 1410. Attention is again called to this list with a recommendation that members secure accommodations in advance. There will be no lack of accommodations in Atlantic City, but the headquarters hotels are apt to be filled before the session, and those who have special preferences as to hotels should secure accommodations at once. The following hotels have been designated as headquarters for the various sections in order that the section members may group themselves in hotels if desired:

OPENING SESSION..... Auditorium Young's New Pier
GENERAL HEADQUARTERS..... Marlborough-Blenheim
PRACTICE OF MEDICINE..... Hotel Dennis
SURGERY AND ANATOMY..... Hotel Chalfonte
OBSTETRICS AND DISEASES OF WOMEN..... Haddon Hall
DISEASES OF CHILDREN..... Hotel Traymore
NERVOUS AND MENTAL DISEASES..... Hotel Brighton
HYGIENE AND SANITARY SCIENCE..... Hotel Seaside
PHARMACOLOGY AND THERAPEUTICS..... Hotel Chelsea
OPHTHALMOLOGY..... Hotel Rudolf
LARYNGOLOGY AND OTOTOLOGY..... Hotel St. Charles
CUTANEOUS MEDICINE AND SURGERY..... Hotel Shelburne
PATHOLOGY AND PHYSIOLOGY..... Hotel Windsor
STOMATOLOGY..... Hotel Royal Palace

OTHER SOCIETIES TO MEET

Many other societies will meet in connection with the Association session, as already announced. The American Society for the Study of Alcohol and Other Narcotics will hold its thirty-ninth annual meeting at Young's Hotel, June 7 to 9. A temperance lunch will be served at 1 p. m., Wednesday, June 9, at Young's Hotel. This will be addressed by many eminent physicians, and is an occasion for the gathering of physicians who are interested in the scientific study of the alcoholic problem. A cordial invitation is extended to all. For programs and further particulars, address Dr. T. D. Crothers, Hartford, Conn.

BUREAU OF INFORMATION, REGISTRATION, POSTOFFICE, ETC

The registration bureau, at which all members should register as soon as they have secured hotel accommodations, is located at the shore end of Young's old pier. Adjoining the registration department is a branch postoffice, as well as telephone and telegraph booths, and bureau of information where one may learn about hotels, transportation, meeting places, entertainments, etc. Occupying the major part of this same pavilion will be the Commercial Exhibit and the Scientific Exhibit, which will receive careful examination from most of the visitors.

ATLANTIC CITY NUMBER

Part of the above announcements are repeated from the Atlantic City Number of THE JOURNAL, May 1, to which readers are referred for further details. That issue contained an illustrated article on Atlantic City and its fame as a watering place. The preliminary programs of the twelve sections were given and much other interesting matter concerning the approaching session.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS will not be noticed. Queries for this column must be accompanied by the writer's name and address, but the request of the writer not to publish name or address will be faithfully observed.

SYNONYMS FOR CHLORID OF LIME

To the Editor.—What is the chemical formula of "hypochlorite of lime"? I found this term in the article "A Case of Poisoning from the Bite of a Rattlesnake," by Charles S. White (THE JOURNAL, May 8, 1909, 141, 1456), which states (p. 1844) that "the best chemical antidote is 2 per cent solution of the hypochlorite of lime."
G. H. PIERCE, M.D., Yonkers, N. Y.

ANSWER—"Hypochlorite of lime" and "chlorid of lime" are terms often applied to the official chlorinated lime. Chlorinated lime is a mixture consisting essentially of calcium chlorid—CaCl₂—and calcium hypochlorite—Ca(OCl)₂—in molecular proportions. Besides these constituents, chlorinated lime also contains calcium hydroxid, calcium carbonate as well as some other calcium salts.

ACID NITROUS ETHER MAY EFFERVESCE WITH POTASSIUM ACETATE

To the Editor.—I should like information as to what occurs in the following prescription:

R
Potassii acetatis (vel citratis)..... 125
Spt. ætherei nitrosi..... 15
Aque q. s. ad..... 125

M

After mixing, a marked ebullition takes place, which is somewhat retarded if glycerin is added. What gas is generated? If it is ethyl nitrite why is that combination prescribed?
O. P.

ANSWER—A neutral potassium acetate or potassium citrate and neutral spirits of nitrous ether, when dissolved in water, should not cause effervescence. Spirit of nitrous ether is liable to be of acid reaction, while potassium acetate and potassium citrate may contain small amounts of carbonate. Under these conditions, when mixed, effervescence will of course occur and carbon dioxide gas will be generated. The addition of glycerin does not prevent, but may slightly retard, the reaction. No decomposition of the medicinal ingredients takes place. It should be remembered, however, that ethyl nitrite, while fairly permanent when dissolved in alcohol (spirits of nitrous ether), is decomposed (hydrolyzed) rather readily by water. The above mixture therefore decomposes gradually when kept.

BILLROTH'S ANESTHESIA SOLUTION

To the Editor.—Will you kindly publish in your Queries and Minor Notes department the formula of Billroth's solution for anesthesia?
E. B. QUILLER, Wilmington, N. C.

ANSWER—Billroth's A. C. E. mixture consists of chloroform 2 parts and ether and alcohol 1 part each.

The Public Service

Army Changes

Memoandum of changes of stations and duties of medical officers, U. S. Army, for the week ended May 22, 1909.

Truhy, A. E., major, ordered to accompany Company A, Eng., to Washington Barracks, D. C., and then return to San Francisco. Winter, Francis A., major, granted leave of absence for 1 month, about July 1.

Baker, David, major, granted leave of absence for 2 months. Reasoner, M. A., 1st lieutenant, granted leave of absence for 24 days; relieved from duty at Fort Caswell, N. C., and ordered to Vancouver Barracks, Wash., for duty.

Stuckey, H. W., 1st lieutenant, M. R. C., relieved from duty in the Philippines Division and ordered to sail August 15 from Manila, P. I., for San Francisco.

Stallman, G. P., 1st lieutenant, M. R. C., ordered from San Francisco to Fort Douglas, Utah, for duty.

Park, Roswell, 1st lieutenant, M. R. C., ordered to active duty, May 26 to June 1, will report to Washington and deliver the address to the graduating class of the Army Medical School, May 29.

Hull, A. R., M. R. C., granted leave of absence to May 31.

McLeod, H. C., 1st lieutenant, M. R. C., relieved from duty in Philippines Division; will proceed on first available transport to San Francisco.

Craig, E. J., D. S., left Fort Leavenworth, Kans., and arrived at Fort Omaha, Nebr., for duty.

Ryan, E. P., D. S., left Fort Leavenworth, Kans., and arrived at Fort Robinson, Nebr., for duty.

Mills, R. H., D. S., ordered to proceed from Monticello, Fla., to Fort Adams, R. I., for duty.

Lafamme, F. L. K., D. S., ordered to proceed from Humford, Mo., to Fort Thomas, Ky., for temporary duty, and, on completion, to Fort Sheridan, Ill., for duty.

Waddell, R. W., D. S., contract annulled at his own request.
Hussey, S. W., D. S., contract annulled at his own request.
Tignor, E. P., D. S., relieved from temporary duty at Fort Monroe, Va., and further duty at Fort Adams, R. I.; will proceed to Fort Slocum, N. Y., for duty.
Carpenter, Alden, D. S., relieved from temporary duty at Fort Slocum, N. Y., and ordered to return to his proper station, Fort Hancock, N. J.
Whinnery, J. C., D. S., left Fort Liscomb, Alaska, and arrived at Fort William H. Seward, Alaska, for duty.

Navy Changes

Changes in the Medical Corps, U. S. Navy, for the week ended May 22, 1909:

Huntington, E. O., surgeon, detached from the Naval Station, San Juan, P. R., and ordered to the Naval Medical School Hospital, Washington, D. C., for treatment.

Cecil, A. B., and Walton, D. C., acting asst.-surgeons, appointed acting asst.-surgeons from May 12, 1909.

Bucher, W. H., surgeon, ordered to report to the president of the Naval Retiring Board at the Navy Yard, Mare Island, Cal., May 31, for examination by the board and thence to treatment at the Naval Hospital, Mare Island, Cal., until further orders.

Fiske, C. N., P. A. surgeon, detached from the Navy Yard, Washington, D. C., and ordered to the Bureau of Medicine and Surgery, Navy Department, Washington, D. C.

Hart, S. D., acting asst.-surgeon, ordered to duty at the Naval Hospital, New York.

Leach, P., medical inspector, commissioned medical inspector, with rank of commander, from April 1, 1909.

Payne, J. H., P. A. surgeon, detached from the *Salem* and directed to wait orders.

Zalesky, W. J., P. A. surgeon, detached from the Naval Station, New Orleans, and ordered to the *Salem*.

Ryder, C. E., P. A. surgeon, detached from the *Vermont* and ordered to the Massachusetts nautical training ship *Nearport*.

Public Health and Marine-Hospital Service

List of changes of stations and duties of commissioned and other officers of the Public Health and Marine-Hospital Service, for the seven days ended May 19, 1909:

White, J. H., surgeon, detailed to represent the service at the annual meeting of the American Medical Association, to be held in Atlantic City, N. J., June 8-11, 1909.

Rosenau, Milton J., surgeon, granted 2 months' leave of absence from April 8, 1909, on account of sickness.

Ramus, Carl, P. A. surgeon, granted 1 day's leave of absence, May 11, 1909, on account of sickness.

Miranda, Rafael U. L., acting asst.-surgeon, granted 1 month's leave of absence from June 1, 1909, and 3 months' leave of absence, without pay, from July 1, 1909.

Small, Edward M., acting asst.-surgeon, granted 10 days' leave of absence from May 19, 1909.

PROMOTIONS

Gardner, Charles H., Blue, Rupert, Oakley, James H., and Sprague, Ezra K., P. A. surgeons, commissioned surgeons, to rank as such from May 1, 1909.

CASUALTY

Wightman, William M., P. A. surgeon, died from yellow fever in Guayaquil, Ecuador, May 16, 1909.

RESIGNATION

Watters, M. H., pharmacist, resigned, to take effect May 13, 1909.

BOARDS CONVENED

Board of medical officers convened to meet at the Marine Hospital, Boston, May 14, 1909, for the purpose of making a physical examination of an applicant for appointment as cadet in the Revenue-Cutter Service. Detail for the board: Surgeon L. L. Williams, chairman; P. A. Surgeon T. W. Salmon, recorder.

Health Reports

The following cases of yellow fever, cholera and plague have been reported to the Public Health and Marine-Hospital Service, ended May 21, 1909:

SMALLPOX—UNITED STATES

California: Sacramento, May 1-8, 5.
Illinois: Alton, April 1-30, 2 cases; Danville, May 2-9, 15 cases; Chicago, May 1-8, 1 case; Galesburg, 1 case; Peoria, April 1-30, 44 cases; Springfield, April 30-May 7, 3 cases.
Indiana: Indianapolis, May 2-9, 1 case; South Bend, May 1-8, 1 case.
Iowa: Council Bluffs, May 3-10, 1 case.
Kansas: Kansas City, May 1-8, 3 cases; Wichita, 2 cases.
Kentucky: Lexington, May 1-8, 1 case; Newport, 2 cases.
Michigan: Saginaw, May 1-8, 7 cases.
Minnesota: Duluth, April 30-May 6, 2 cases.
Missouri: Kansas City, April 17-May 8, 10 cases; St. Joseph, March 27-April 3, 1 case; St. Louis, May 1-8, 1 case.
Montana: Butte, April 20-May 4, 7 cases; Great Falls, April 24-May 1, 1 case.
New Jersey: Camden, May 1-8, 2 cases; Trenton, 1 death.
New York: Little Falls, April 24-May 8, 2 cases.
Ohio: Ashtabula, April 17-May 8, 2 cases; Cincinnati, April 30-May 6, 9 cases; Columbus, May 1-8, 1 case.
Tennessee: Nashville, May 1-8, 1 case.
Virginia: Richmond, April 30-May 1, 1 case.
Washington: Spokane, April 30-May 1, 4 cases.
Wisconsin: La Crosse, May 1-8, 1 case.

SMALLPOX—INSULAR

Philippine Islands: Manila, March 27-April 3, 3 cases, 1 death.

SMALLPOX—FOREIGN

Canada: Halifax, April 24-May 1, 1 case; Yarmouth, May 1-8, 1 case.
Ceylon: Colombo, Feb. 13-March 27, 37 cases, 8 deaths.
China: Amoy, March 27-April 3, present; Canton, March 20-27, 20 cases.
Egypt: Cairo, March 25-April 8, 28 cases, 10 deaths.
Gibraltar: March 26-May 2, 1 case.
India: Bombay, April 6-13, 15 deaths; Calcutta, March 26-April 3, 281 deaths; Rangoon, 14 deaths.
Italy: General, April 18-25, 9 cases; Naples, 13 cases, 1 death.
Java: Batavia, March 20-April 3, 7 cases, 2 deaths.
Manchuria: Dalny, April 3-10, 5 cases, 1 death.
Mexico: Chihuahua, April 18-May 2, 4 cases; Monterey, April 25-May 2, 16 deaths.
Russia: Batoom, March 1-31, 2 cases; Moscow, April 10-17, 28 cases, 13 deaths; Odessa, April 3-17, 23 cases, 2 deaths; Niga, April 18-21, 2 cases; St. Petersburg, March 27-April 10, 46 cases, 11 deaths; Warsaw, Feb. 13-20, 2 deaths.
Siam: Bangkok, Feb. 1-28, 111 cases, 72 deaths.
Spain: Barcelona, April 19-26, 5 deaths; Valencia, April 17-24, 10 cases.
Straits Settlements: Singapore, March 20-27, 1 death.

YELLOW FEVER

Barbados: April 25-May 1, 4 cases.
Brazil: Para, April 10-17, 6 cases, 6 deaths.
Ecuador: Guayaquil, March 20-April 3, 72 cases, 34 deaths.

CHOLERA—INSULAR

Philippine Islands: Provinces, March 25-April 3, 177 cases, 82 deaths.

CHOLERA

India: Bombay, April 6-13, 97 deaths; Calcutta, March 26-April 3, 129 deaths; Rangoon, 8 deaths.
Russia: St. Petersburg, April 22-28, 12 cases, 1 death.

PLAGUE

Arabic: Mascat, April 14, 1 case, 1 death, imported.
Australia: New Castle, March 1-31, 1 case, imported; Sydney, March 6-12, 4 cases, 1 imported.
Chile: Antofagasta, April 7, 10 cases; Iquique, April 8, 17 cases.
China: Amoy, March 27-April 3, present; Chang Chew, epidemic.
Ecuador: Babohoyo, March 20-27, 2 cases; Guayaquil, March 20-April 3, 34 cases, 12 deaths.
India: Bombay, April 6-13, 370 deaths; Calcutta, March 27-April 3, 94 deaths; Rangoon, 29 deaths.
Japan: Kobe, April 3-17, 2 cases; Formosa, March 27-April 10, 123 cases, 99 deaths.
Peru: General, April 10-17, 29 cases, 19 deaths; Callao, 4 cases, 3 deaths; Lima, 10 cases, 4 deaths.

Marriages

R. C. BOWMAN, M.D., to Miss Blanche Smith, both of Philadelphia, May 12.

LEROY H. Saxe, M.D., to Miss Estelle S. Gerhart, both of Telford, Pa., April 28.

CHARLES N. ALLISON, M.D., Canton, Ill., to Miss Fern Barnes of Paulding, Ohio, May 1.

MARY L. D. BICKINGS, M.D., to Harold Thornton, both of Philadelphia, Pa., April 30.

WILLIAM W. LEWIS, M.D., St. Paul, Minn., to Miss Barbara Haug of Duluth, March 22.

ANDREW COLIN GILLIS, M.D., Baltimore, to Miss Bertha Fischer, at Baltimore, May 4.

REV. A. HAND, M.D., Camden, N. J., to Miss Elizabeth Hughes Blattner of Cape May, N. J., May 11.

CORDY N. PATE, M.D., Fort Smith, Ark., to Miss Ione Gayden of Winona, Miss., May 7.

DON C. HUGHES, M.D., Findlay, Ohio, to Mrs. Laura Lingelfelter, at Chicago, April 20.

VIRGINIUS DABNEY, M.D., to Miss Ada Louise Newlands, both of Washington, D. C., May 18.

WILLIAM H. STRENG, M.D., Spring Grove, Ill., to Miss Ada Richardson of Richmond, Ill., recently.

EDGAR S. McILVAIN, M.D., Manila, P. I., to Miss Saidee Dougherty of Nashville, Tenn., May 12.

WALTER BAER WEIDLER, M.D., Lancaster, Pa., to Miss Grace Langley at New York City, April 20.

DWIGHT GORDON SMITH, M.D., Washington, D. C., to Miss Emily Griffin Reid, at Washington, May 11.

C. S. FLOYD, M.D., Loganville, Ga., to Miss Birdie Scott of Norwood, Ga., at Stone Mountain, Ga., May 6.

STANFORD K. WINSOR, M.D., Anand, British India, to Miss Bessie Marie Carroll of Chicago, May 11.

WILLIAM THEOPHILUS CHAPMAN, M.D., Uniontown, Pa., to Miss Wilbia May Newson of Monessen, Pa., May 12.

Deaths

Thomas J. Happel, M.D.

Dr. Thomas J. Happel, one of the most earnest, faithful and efficient members of the American Medical Association, died at his home in Trenton, Tenn., May 24, from brain tumor, after a protracted illness, aged 62.

He was born in Greensboro, Alabama, Jan. 24, 1847. Enlisted as a boy as a soldier in the Confederate Service; he was taken prisoner in 1864, and imprisoned in Mobile until the close of the Civil War.

He was graduated from the medical department of the University of Virginia, Charlottesville, in 1871, and in the following year from New York University.

He was a member of the American Medical Association for many years, vice-president in 1897, a member of the Board of Trustees from 1898 until the time of his death and chairman of the board from 1901 to 1908. Those who were present at the meeting of the Association in Denver in 1898 will remember the splendid record he made as presiding officer on that occasion when the notable discussion of the rules of ethics took place.

He served as president of the Tennessee State Medical Association, of the Gibson County Medical Association, the Tri-State Medical Association of Tennessee, Arkansas and Mississippi, and West Tennessee Medical and Surgical Association. He was health officer of Gibson County for sixteen years, and president of the Trenton board of health for twenty-eight years and secretary and treasurer of the State Board of Medical Examiners since its organization in 1889, and during this time compiled and issued the state directory, which stands as a monument to his painstaking labor. He also served as vice-president of the Association of Southern Railway Surgeons, and the National Association for the Study and Prevention of Tuberculosis. He was for many years local surgeon of the Mobile and Ohio Railroad, and a member of the local board of pension examining surgeons.

For a number of years he had been a member of the Board of Aldermen of Trenton, and to him is given the credit of the high position that city holds in regard to paving, light, and water supply, as well as low taxation.

Dr. Happel was always in the forefront of all work for the good of the community in which he lived, and the profession which he honored. He was known throughout the state and the South, and was universally beloved. He was one of the most esteemed and most conscientious members of the Board of Trustees of the American Medical Association and was always ready to give freely of his counsel and his time for the upbuilding of the Association. Those who have had the pleasure of being associated with him will not soon lose the inspiration of this noble life.

William Martin Wightman, M.D. Cooper Medical College, San Francisco, 1899; a member of the American Medical Association; who entered the Public Health and Marine-Hospital Service, in 1902, a year later was made assistant surgeon, and in 1908 was promoted to the grade of passed assistant surgeon; one of the ablest of the younger officers of the service; died from yellow fever, May 16, at his station in Guayaquil, Ecuador, where he had been sent to observe and take measures for preventing the spread of yellow fever, aged 33.

William L. Steele, M.D. Medical College of the State of South Carolina, Charleston, 1857; formerly president of the Association of Montana Pioneers; for one term sheriff, for ten years coroner, and for two terms treasurer of Lewis and Clark county, Mont.; for four years state senator; for one term alderman, and for three terms mayor of Helena; died at his home in Helena, May 16, from cerebral hemorrhage, aged 76.

Isaac Francis Galloupe, M.D. Harvard Medical College, Boston, 1849; a member of the Massachusetts Medical Society; surgeon of the Seventeenth Massachusetts Volunteer Infantry and later brigade and division surgeon and medical director of the Eighteenth Army Corps during the Civil War; and a prisoner in Libby Prison, Richmond, Va.; formerly city physician and a member of the board of U. S. pension examining surgeons and of the school board of Lynn, Mass.; died at his home, May 17, from paralysis, aged 85.

Charles M. Thompson, M.D. College of Physicians and Surgeons, Chicago, 1883; a member of the Michigan State Medical Society; a member of the first village council and at one time health officer of Elk Rapids, Mich.; died at his home from aneurism of the aorta, May 10, aged 44.

Charles Bates Tower, M.D. Harvard Medical School, Boston, 1881; died at his home in Cambridge, Mass., May 14, aged 66.

William R. Bird, M.D. College of Physicians and Surgeons, Baltimore, 1880; a member of the Medical Society of the State of Pennsylvania; died at his home in Chester, May 13, from pneumonia, aged 51. At a special meeting of the Delaware County Medical Society, a committee was appointed to prepare and present suitable resolutions regarding the death of Dr. Bird.

Gerardus Hilles Wynkoop, M.D. College of Physicians and Surgeons, New York City, 1866; a member of the Medical Society of the State of New York, consulting surgeon to the Northern Dispensary, New York City; visiting surgeon to St. Luke's and the Roosevelt hospitals; died at his home May 16, from peritonitis, three days after an operation for appendicitis, aged 65.

C. Helge Browall, M.D. University of Stockholm, Sweden, 1895; local surgeon at Ada, Okla., for the Oklahoma Central Railroad; president of the local health board, and city physician of Ada; died in the St. Vincent de Paul Sanitarium, Sherman, Texas, May 14, from septicemia, due to an operation wound, aged 33.

Rachel S. Skidelsky, M.D. Woman's Medical College of Pennsylvania, Philadelphia, 1894; a member of the Medical Society of the State of Pennsylvania and prominent as a philanthropist; physician to the Home for Jewish Girls, Philadelphia; died at her home in that city, May 13, from pneumonia, aged 53.

Salvatore Gomez, M.D. Long Island College Hospital, 1891; formerly acting assistant surgeon P. H. and M.-H. Service at Gibara, Cuba; for eight years port physician at Sastia, and since May head physician of the Spanish-American Iron Company's Hospital; died in that institution, May 16, aged 47.

Charles E. Witbeck, M.D. Albany (N. Y.) Medical College, 1866; a member of the American Medical Association; president of the staff of the Cohoes, N. Y., Hospital; for many years health officer and member of the board of health of Cohoes; died at his home, May 13, from nephritis, aged 65.

THOMAS J. HAPPEL, M.D., 1847-1909

John Eberle Payton, M.D. Willamette University, Salem, Ore., 1877; a member of the American Medical Association; a member of the Board of Health and a prominent practitioner and citizen of Redlands, Cal.; died from tuberculosis, at the Pottenger Sanatorium, Monrovia, Cal., May 10, aged 51.

George W. Fisher, M.D. Georgetown University, Washington, D. C., 1870; a veteran of the Civil War; and for several years a clerk in the record and pension division of the War Department, Washington; died May 17, at his home in Anacostia, Washington, D. C., aged 69.

John Grove Speer, M.D. Transylvania University, Lexington, Ky., 1830; for a time probate judge of Macon county, Ill., and a resident of Decatur, and later a practitioner of Floydshurg, Ky.; died at the home of his son in Alton, Ky., from influenza, May 2, aged 100.

Alta Fremont Cook, M.D. University of Michigan, Ann Arbor, 1881; a member of the American Medical Association; acting assistant surgeon U. S. Army and M.-H. Service; was found dead in his office in Sandusky, Ohio, May 14, from valvular heart disease, aged 58.

John C. Edward Kaiser, M.D. University of Berlin, Germany, 1870; lecturer on histology and embryology at his alma mater in 1874; and professor of anatomy at the Humboldt Academy, Berlin, in 1876; died at his home in Green Bay, Wis., May 17, from heart disease, aged 56.

Joseph Edgar Grimsley, M.D. University of Virginia, Charlottesville, 1883; of Greensboro, N. C.; a member of the Medical Society of the State of North Carolina; died in St. Leo's Hospital, Greensboro, May 15, from septicemia, due to an operation wound, aged 49.

Joseph B. Kinley, M.D. Hahnemann Medical College, Chicago, 1885; dean of the Denver College of Physicians and Surgeons; died suddenly May 13, from concussion of the brain following a fall due to vertigo, at a banquet of the graduating class of the college, aged 49.

William Long, M.D. Georgetown University, Washington, D. C.; chief chemist in the Bureau of Engraving and Printing, Washington; a chemist, linguist, and musician of note; died in the Emergency Hospital, Washington, May 14, from cerebral hemorrhage, aged 50.

Charles Appleton Packard, M.D. Medical School of Maine, Brunswick, 1856; a fellow of the American Academy of Medicine; for 20 years physician to the Military and Naval Orphans' Hospital, Bath, Maine; died at his home, March 23, from arteriosclerosis, aged 80.

Francis Marion Savage, M.D. Louisville, 1870; for several years president of the U. S. board of pension examining surgeons at South McAlester, I. T.; twice postmaster of Hartshorne, Okla.; a veteran of the Civil War; died at his home in Hartshorne, Nov. 8, 1908, aged 76.

Robert H. Seymour, M.D. University of Dublin, Ireland, 1870; a member of the State Medical Association of Texas; and for several years secretary of the Fayette County Medical Society; died at his home in Warrenton, March 26, aged 57.

Durell Shepard, M.D. Yale University, New Haven, 1864; a member of the American Medical Association; acting assistant surgeon in the Army during the Civil War; died at his home in West Haven, Conn., from senile debility, May 16, aged 77.

John S. Lupton, who retired from practice forty-five years ago on account of deafness and was the pioneer fruit grower of the Shenandoah Valley; died at his home in Winchester, Va., Nov. 6, 1908, from paralysis, aged 80.

Joshua Swigert, M.D. Washington University, Baltimore, 1863; formerly of Brazil, Ind.; died in the Cook County Institutions, Dunning, Ill., May 3, from exhaustion, due to chronic morphinism, aged 71.

Samuel G. Statler, M.D. Jefferson Medical College, Philadelphia, 1851; a member of the Medical Society of the State of Pennsylvania; died at his home in Alum Bank, May 13, from senile debility, aged 82.

Asa Walter Jayne, M.D. Homeopathic Medical College, New York City, 1879; of North Tonawanda, N. Y.; coroner of the first Niagara District; died in Buffalo, Nov. 16, 1900, from pneumonia, aged 58.

Arthur C. L. Fox, M.D. McGill University, Montreal, 1898; of Montreal; formerly an oarsman of repute in western Canada; died in the Royal Victoria Hospital, Montreal, March 31, aged 44.

Thomas Hall, M.D. Harvard Medical School, Boston, 1866; of Boston, a member of the Massachusetts Medical Society; died in Chelmsford Center, Mass., May 14, from cerebral embolism, aged 70.

Alfred Knox Middleton, M.D. Louisville, 1851; surgeon in the Confederate Service during the Civil War; died at his home in Arlington, Texas, April 14, 1908, from senile debility, aged 78.

Alfred P. Pierce, M.D. University of Buffalo, N. Y., 1898; a member of the Medical Society of the State of Pennsylvania; died at his home in Bradford, Aug. 15, 1908, from uremia, aged 45.

Sam L. Holcomb, M.D. St. Louis; for many years a practitioner of Pike county, Mo.; died at the home of his brother in Cherokee, Texas, Oct. 17, 1908, from cerebral hemorrhage, aged 73.

John Farquhar McDonald, M.D. Harvard Medical School, Boston, 1868; formerly of Elmsdale and Hopewell, N. S.; died at his home in Shubenacadie, N. S., in November, 1908, aged 71.

Samuel Gager Johnson, M.D. New York University, New York City, 1878; died at his home in Bozrah, Conn., April 3, from influenza and secondary anemia, aged 60.

William Devereaux Kendall, M.D. University of Pennsylvania, Philadelphia, 1858; a Confederate veteran; died at his home in Paris, Tenn., May 8, aged 64.

Bradley Crippen, M.D. Western Reserve University, Cleveland, 1861; a veteran of the Civil War; died at his home in Coldwater, Mich., March 17, aged 64.

Andrew J. Bobbs, M.D. Medical College of Ohio, Cincinnati, 1854; a pioneer practitioner of Marion, Ind.; died at his home in that city, May 13, aged 76.

Margaret Richardson, M.D. Woman's Medical College of Pennsylvania, Philadelphia, 1853; died at her home in Norristown, Pa., May 15, aged 91.

Manfred H. McDonald, M.D. Bellevue Hospital Medical College, New York City, 1873; died at his home in Hempstead, N. B., February 28, aged 62.

William S. Moslander, M.D. Hahnemann Medical College, Philadelphia, 1889; died at his home in Camden, N. J., May 12, from tuberculosis, aged 49.

Theodore Miller, M.D. New York University, New York City, 1873; died at his home in Califon, N. J., May 14, from lung disease, aged 60.

Alter Louis Slonaker, M.D. Western Pennsylvania Medical College, Pittsburg, 1889; died at his home in East End, Pittsburg, May 14, aged 46.

Cornelius W. Parker, M.D. Southern Botanical-Medical College, Macon, Ga., 1853; died at his home in Atlanta, May 15, aged 80.

George W. Landis, for many years a practitioner of North Carolina; died at his home in Durham, Sept. 22, 1908, aged 67.

John Hammel, M.D. Kentucky School of Medicine, Louisville, 1880; died at his home in Buckskin, Ind., May 12, aged 54.

David Randall, M.D. St. Louis, 1836; died at his home in Norwalk, Cal., Sept. 18, 1908, from senile debility, aged 98.

James Henry Payne, M.D. New York University, New York City, 1849; died at his home in Boston, May 14, aged 85.

Book Notices

THERAPEUTICS OF THE CIRCULATION. Eight Lectures Delivered in the Spring of 1905 in the Physiologic Laboratory of the University of London. By **Lauder Brunton, Kt., M.D., D.Sc., LL.D.** (Edin.), LL.D. (Aberd.), F.R.C.P., F.R.S., Consulting Physician to St. Bartholomew's Hospital. Cloth. Pp. 280, with illustrations. Price, \$1.50. Philadelphia: P. Blakiston's Son & Co., 1908.

These lectures, delivered in 1905, have been revised by the author. The reader who expects to find only a treatise on therapeutics of the circulation will be disappointed because 108 of the 280 pages in the book are devoted to physiology and the instruments by which this subject can be studied in the laboratory and clinic. This portion of the book is written in Brunton's usual style, and is full of his own observations and interpretations of facts. Lectures 4 and 5 discuss the therapeutics of various heart diseases and conditions. The two succeeding chapters describe the physiologic and therapeutic action of such drugs as digitalis, adrenalin, strychnin, caffeine, amyl nitrite, isobutyl nitrite, hydroxylamin, nitrogly-

cerin, nitroerythrin, nitromannite, tobacco, aconite, general and local bleeding, diet and regimen, Nauheim and Oertal treatments, exercise, etc. Several appendices and full indexes follow these lectures. This book is full of the interest which Brunton's personality gives to all his writings. It also possesses the defect of most lectures, in that many topics are too briefly considered and others too much in detail. The book is attractive and copiously illustrated.

TUBERCULOSIS OF THE NOSE AND THROAT. By Lorenzo B. Lockard, M.D., Laryngologist and Rhinologist to the Jewish Consumptives' Relief Society Sanatorium. Cloth. Pp. 368, with illustrations. Price, \$5. St. Louis: C. V. Mosby Co., 1909.

Dr. Lockard reviews the entire subject of tuberculosis of the larynx, pharynx and nose. He begins with a digest of the history of the subject, follows this with well-selected statistics, and then enters into clinical details and treatment. Throughout the treatise he shows thorough familiarity with the literature, as well as extensive personal experience. His own experience leads him to take definite position regarding many questions under discussion. This makes the book a satisfactory one for clinical reference. Notwithstanding its bulk, the work contains neither unnecessary repetitions nor padding; it can be recommended to any one interested in the subject. Its therapeutic teaching is judicious and conservative, though often rather optimistic—the optimism being justified, no doubt, by the climatic advantages of Dr. Lockard's practice. It is to be regretted, perhaps, that he takes so reserved a position toward all forms of tuberculin treatment, even though this treatment has not yet been successfully applied to tuberculous diseases of the throat. The influence of tuberculin treatment on tuberculosis in other parts of the body has been so often demonstrated that laryngologists can not afford to be indifferent to it. The numerous laryngoscopic illustrations may be somewhat criticized from an artistic point of view, but for clinical purposes they are good and useful.

OPERATIVE MIDWIFERY. By J. M. Munro Kerr, M.B., C.M., Glas., Fellow of the Faculty of Physicians and Surgeons, Glasgow. Cloth. Pp. 705, with illustrations. Price, \$6.00. New York: William Wood & Co., 1908.

This work deals mainly with the abnormal part of obstetrics, and in this respect at least in the English language, stands alone. Dr. Kerr dwells at length on causes of dystocia, and attempts to impress the necessity of an early, careful, scientific examination of every pregnant woman. These chapters abound in most excellent advice, and can be read frequently with profit. While Dr. Kerr is not dogmatic, still he has some set ideas which do not appeal to us on this side of the water. For instance, he is enthusiastic over the symphyseotomy operation; says that he can see no reason to abandon it, and presents statistics which really give him ground for such an opinion. Pubiotomy, he says, will not displace it, or at least he is willing to wait until the pubiotomy craze is over and we can draw a calm dispassionate conclusion of its merits. We in America have never had a high opinion of the operation of symphyseotomy, and, as he says, most of the criticism has come from those who have never performed it. He admits that there are no fast rules to be followed in every case, and says that one is not long in obstetrical practice without finding out that Nature in parturition, although generally following a certain course, refuses to be trammelled by hard and fast rules. It is for the accoucheur to bear in mind, however, Nature's limits. The mistake is often made of forgetting these limits and of interfering with Nature in cases in which a little patience would render such interference unnecessary.

Diagnosis, examination by external palpation and auscultation and contracted pelvis are considered more fully than is usual. Dr. Kerr has little faith in instrumental measurement of the internal pelvis, and relies principally on the hand and on the judgment which comes from experience. Radiography, in estimating the size of the pelvis, or relation of the head to the pelvis, has not proved of value in his hands. He advises prophylactic cephalic version in breech cases in the last week or two of pregnancy, a treatment which has many warm advocates, but which seems to be open to criticism. The 294 illustrations are mostly original and highly instructive.

THE HERTER LECTURES (NEW YORK, 1908) ON THE FLUIDS OF THE BODY. By Ernest H. Starling, M.D., F.R.C.P., F.R.S., Jodrell Professor of Physiology in the University College, London. Cloth. Pp. 186, with illustrations. Price, \$2. Chicago: W. T. Keener & Co., 1909.

This book contains eight lectures given all but one under the Herter foundation at the Bellevue Hospital and University Medical School in 1908. The subjects discussed are the physical properties of protoplasm, the osmotic relationships of cells, the intake of fluid, the exchange of fluids in the body and the production of lymph, the absorption of the interstitial fluids, the output of fluid, the fluid balance of the body, and the causation of dropsy. The presentation is interesting. Dr. Starling speaks his own views, which no doubt will stimulate discussion among workers in this field. To physicians who desire to follow the growth of knowledge of the physico-chemical processes in the body, the book is recommended most heartily as sure to be read with interest and profit.

THE PROBLEM OF AGE, GROWTH AND DEATH. A Study of Cyto-morphosis Based on Lectures at the Lowell Institute, March, 1907. By Charles S. Minot, LL.D., D.Sc., James Stillman Professor of Comparative Anatomy in the Harvard Medical School. Cloth. Pp. 280, with illustrations. Price, \$2.50. New York: G. P. Putnam's Sons, 1908.

In this volume the distinguished author summarizes the results of his scientific work on the problem of age, growth and death. It appears that for twenty-five years and more this problem has occupied his scientific interest. Desire to get at actual facts led to a long and comprehensive series of observations on the growth of certain animals in order to secure vantage ground for attack on the changes affected by age, changes that have been studied but little in a systematic way. Says Dr. Minot: "Age causes many progressive changes in the organism, but none which are more obvious and more accessible to exact study than those of growth." Most of the very valuable observations on growth as a function of age were made on guinea-pigs, the growth being measured by weight.

The book itself is divided in six chapters, the subjects being the condition of old age, cytomorphosis, the cellular changes of age, the rate of growth, differentiation and rejuvenation, regeneration and death, and the four laws of age.

The four laws of age, which in a way constitute the conclusions, are: First, rejuvenation depends on an increase of the nuclei; second, senescence depends on the increase of the protoplasm, and on the differentiation of the cells; third, the rate of growth depends on the degree of senescence; fourth, senescence is at its maximum in the very young stages, and the rate of senescence diminishes with age.

Dr. Minot carefully refrains from any suggestions as to the actual causes of the increase in the amount of protoplasm that characterizes senescence, confining himself entirely to morphologic considerations.

The book constitutes an important contribution to general biology. The presentation is excellent, the style clear and lucid.

THE THEORY OF IONS. A Consideration of Its Place in Biology and Therapeutics. By William Tibbles, M.D. (Hon. Causa), Chicago, LL.D., L.R.C.P.E., M.R.C.S., L.S.A., etc. Cloth. Pp. 131. Price, \$1. New York: Reiman & Co., 1909.

Dr. Tibbles attempts to account for all biologic processes on the basis of ionization. As practically all chemical reactions are between ions, and as all biologic processes are directly or indirectly the result of chemical reactions, the proposition would seem to be self-evident. The reader will find a brief semi-popular discussion of the principles of the ion theory, but the logic of much of Dr. Tibbles' theorization is difficult to follow. His facts seem to have been obtained from standard authorities and therefore are reliable.

MILITARY HYGIENE. By R. H. Firth, Lieut.-Colonel Royal Army Medical Corps. Cloth. Pp. 299. Price, \$1.40. Philadelphia: P. Blakiston's Son & Co., 1908.

This is a brief, succinct and practical manual of sanitation for soldiers, in which Colonel Firth takes up the causes of disease; the preventable diseases; principles of disease prevention; the recruit; physical training of the soldier; the barrack; water supply, food, clothing and equipment; the work of the soldier, the march, and the camp.

How to Nurse Sick Children. By Charles West, M.D., Founder of and Late Physician to the Hospital for Sick Children, Great Ormond Street. With a Preface by George F. Still, M.D., Physician to Out-Patients, The Hospital for Sick Children. New Edition. Cloth. Pp. 52. Price, 40 cents. New York: Longmans, Green & Co., 1908.

While this book contains little that is likely to interest the physician, it should prove of value to mothers and nurses. It contains much practical advice and common sense, especially on points generally omitted from ordinary text-books of nursing. Emphasis is laid on the importance of truthfulness in dealing with children.

LEHMANN'S MEDIZINISCHE HANDATLANTEN. BAND XVII/1. Atlas und Grundriss der gerichtlichen Medizin, unter Benutzung von E. v. Hofmann's Atlas der gerichtlichen Medizin. Herausgegeben von Dr. Georg Puppe, Professor der gerichtlichen Medizin in Königsberg i. P. Mit 70 vielfarbigen Tafeln und 204 schwarzen Abbildungen. Paris I and II. Price, \$5.00 per set. München: J. F. Lehmann's Verlag, 1908.

This work of about 700 pages appears in the form of two rather small volumes. It deals with the autopsy findings in death from any cause which may have a legal or forensic bearing and these findings are not only clearly described, but excellently illustrated in black and white and in colors. In addition to this methods of identification of both the living and the dead are described, together with the German laws governing the making of autopsies for medicolegal purposes and the giving of expert testimony and of certificates or opinions by medical men. The work contains much that is of value to physicians in general as well as to those who are especially engaged in medicolegal work.

ASSOCIATION OF AMERICAN PHYSICIANS

Twenty-fourth Annual Meeting, held at Washington, D. C., May 11-12, 1909

The President, DR. VICTOR C. VAUGHAN, Ann Arbor, Mich., in the Chair

Officers Elected

The list of officers elected appeared in THE JOURNAL, May 22, page 1675.

The President's Address: The Physical Basis of Life

DR. VICTOR C. VAUGHAN, Ann Arbor, Mich.: The living cell is made up of active labile molecules, and these molecules consist of numerous atoms, and each atom contains a large group of electrons; atoms and electrons are in ceaseless, rhythmic motion, while groups of atoms are being constantly cast off of the molecule and replaced by new groups split off from matter outside the molecule. Metabolism, the one characteristic phenomenon of living matter, involves intramolecular change; consequently, the molecule and not the cell is the unit of life. Life is function and not form, and, moreover, it is a molecular function. In multicellular animals, such as man, we have colonies, or groups of cells, or organs, bound together. Each kind of cell has its own peculiar molecular composition, and through these living molecules the work of

the organ is accomplished. We have heard much of late concerning the influence of mind on the body, and many who speak on this subject seem to assume that there is some entity, called mind, that controls the body, to which it is superior, and apart from which it may exist. This dualistic doctrine is as old as the philosophy of Plato; it always has been and remains to-day a dogma without scientific support, and as a hypothesis it has led to the discovery of no scientific fact. Every attempt to apply it to the treatment of disease has led to the development of conscious or unconscious charlatanism, and has resulted in more or less marked atavism. The term functional disease is now being used by those who know but little concerning the functions of the body in either normal or abnormal states. It seems to be inferred or assumed by those using this expression that a mysterious power has been given to some to set the mechanism of the disordered body aright. In truth, we have no evidence of the existence of a functional disease as thus understood. We may not always be able to find where the basic fault lies, but shall we for this reason stop looking for it, shut our eyes, give over our search and ask some individual quite ignorant of the body and its functions to undertake the task of inducing harmonious activities?

Three Cases of Amaurotic Family Idiocy with an Anatomic Study of One: A Preliminary Report

DRS. HARLOW BROOKS and HENRY WANDLESS, New York: This is a rare disease, affecting several members of the same family, and characterized by distinct lack of mental development, by a progressive weakness of all the muscles of the body, and by a defect in vision. It is generally fatal, the children dying as a rule in a condition of complete marasmus before the end of the second year of life. The pathology of the disease has been chiefly studied by ophthalmologists and neurologists. In the region of the macula lutea a whitish spot appears, in the center of which a cherry red point is seen. In the encephalon and throughout the entire spinal cord very extreme grades of ganglion cell degeneration are shown. The general consensus of opinion is that the degeneration is an aplastic one, a failure to progress and consequently a cell deterioration. Another theory is that the disease is toxic in origin. In the case subjected to special study, besides the changes usually found in cases of amaurotic family idiocy, we have found marked and more or less characteristic alterations in the thymus body and in the adrenal and pituitary glands. These lesions are of such nature as strongly to suggest long-standing atypical functional activity. With our certain knowledge of the dependency for proper growth and function of the central nervous tissues on the normal activity of these bodies, it seems justifiable to assume a possible causal relationship in this condition, though it is quite possible that these lesions in the ductless glands are merely concomitant or associated ones.

DISCUSSION

DR. B. SACHS, New York: I am not yet willing to go to the length Dr. Brooks has gone regarding the cause of the disease, although his findings in this case are extremely interesting. I will say, in justification of others who have examined these cases, that the attempt has been made to examine every single organ of the body, and no changes have been found in the adrenals, thymus or pituitary gland. I think the proper view to take of the disease is that in these children the defect in the nervous system is such that the highest nerve elements are only equipped for a certain and a very limited function. In other words, that they are so started in life that they can only perform their function properly for a number of months and then give out, and, in consequence of this, undergo degeneration. I can not conceive that any family disease should be due to toxic causes and nothing else.

Visceral Angioneuroses

DR. S. SOLIS COHEN, Philadelphia: I have made previous communications on the subject of vasomotor ataxia (1892-1894-1896-1898). The condition is by no means rare, and is marked in certain families, especially in those exhibiting her-

editary tendency to disorders of metabolism, gout, diabetes, etc. It exists in some persons without causing any inconvenience. When, however, disease of any kind or from any cause arises in such persons, their constitutional peculiarities modify the symptomatology. An incautious observer, or one who does not recognize the significance of the vasomotor phenomena, may easily be led astray. This is especially the case in maladies attended with hemorrhage—whether slight or profuse—with cardiac disturbance, with headache, with painful crises or with serous discharges. The dependence of certain asthmatic paroxysms on what may be termed bronchial urticaria was emphasized in my previous communications and was well known before. Less familiar are the angioneurotic edemas of the base of the tongue and of the larynx, which cause suffocative paroxysms and may threaten death. Still rarer in literature and in practice is the recognition of angioneurotic conditions of the gastroenteric tract, the liver and the kidney. Certain utero-ovarian symptoms may by analogy be ascribed to similar processes, and there is no reason for excluding any viscus or tissue supplied with vessels. Considerable doubt and difficulty arises when cerebral symptoms are manifested. I have seen two cases in which operations for appendicitis were done because of painful abdominal crises of angioneurotic origin, and normal appendices were found. Evidence from morbid anatomy supporting the diagnosis of visceral angioneurosis is, from the nature of the process, practically unattainable; except negatively in the rare instances of surgery and the still rarer instances which can be followed throughout life and after death. Organic disease or deformity may coexist with angioneurotic disorder, as exemplified by one of my cases in which malposition of the kidney was responsible for some of the symptoms, and these, together with general nutrition, were relieved by successful operation. Furthermore, it is my conviction, from cases observed over prolonged periods, that actual disease of the vessels (angiosclerosis) may eventually be set up, pseudoangina, for example, becoming veritable angina. A number of cases were seen in which Graves' syndrome developed under observation, from a basis of slight vasomotor ataxia, and one in which an incomplete Raynaud's syndrome similarly developed. A notable case is one which began with uremic symptoms, including suppression, and in which the patient exhibits no evidence of nephritis but has passed through and recovered from the full syndrome.

DISCUSSION

DR. WILLIAM OSLER, Oxford, England: Largely through Dr. Cohen's stimulation we have of late years gained a good deal of information regarding these angioneurotic edemas. The group which is associated with skin lesions is most important to us practically, because undoubtedly the same lesions may occur in the abdominal organs, particularly the stomach and intestines, with severe symptoms, as vomiting, nausea, pain, and all the features of a severe attack of colic. Such features may occur owing to changes in the walls of the stomach or intestines the exact counterpart of those changes which occur in the skin. Surgeons know this. They have operated in a number of cases, supposing the patient had appendicitis, and the localized edema in the stomach and intestines has been seen—an edema which is exactly like angioneurotic edema. This is a very interesting group of cases which may or may not be associated with skin lesions. There are cases in children undoubtedly in which these features have occurred for years and years before any skin lesion has occurred. I saw only a few months ago a case that was about to go to operation for supposed gallstones, and fortunately just a little before my visit there came out a crop of urticaria and one characteristic patch of angioneurotic edema. Of course the patient was not operated on. It turned out that from childhood the patient had had attacks of colic, some of which had been associated with these cutaneous outbreaks. Another group that we may recognize is that which is associated with arteriosclerosis and spasm of the vessels of the abdomen. I think these cases that we call angina abdominalis, cases with symptoms like angina pectoris, in all probability are due to spasm of the visceral vessels.

(To be continued)

AMERICAN THERAPEUTIC SOCIETY

Tenth Annual Meeting, held at New Haven, Conn., May 6-8, 1909

The President, DR. FREDERIC H. GERRISH, Portland, Maine, in the Chair

The address of welcome was delivered by Arthur T. Hadley, LL.D., president of Yale University, and the response by Dr. Thomas E. Satterthwaite, New York.

The report of the standing committee on therapeutic research, which was read by the secretary of the committee, Dr. H. C. Wood, Jr., Philadelphia, was on "The Quality of Fluidextract of Ergot at Present on the Market."

The obituary of Dr. Robert Reyburn, president of the society, 1906 to 1907, written by Dr. H. H. Barker, was read by the secretary, Dr. Noble P. Barnes, Washington, D. C.

Officers Elected

The officers elected were given in THE JOURNAL, May 15, p. 1591.

President's Address: The Therapeutic Value of Hypnotic Suggestion

DR. F. H. GERRISH, Portland, Maine: This subject has been surrounded with much entirely unnecessary mystery, and there has been a great deal of confusion in regard to it, not only among the public at large, but also in the minds of physicians. There can be no doubt, however, that it has a legitimate field in medicine, and when I was in general practice I made use of it for many years, with satisfactory results in a number of cases. The methods of applying this mode of treatment can be easily acquired, and it is a mistaken notion that it requires any special qualifications on the part of the operator for its successful employment.

The Standardization of Materia Medica Products

DR. F. E. STEWART, Germantown, Pa.: This subject embraces a much wider scope than is usually realized. It is impossible to carry out any systematic plan of standardization without considering the matter from the broadest possible point of view, and I believe that the present conditions call for the establishment of a strong central committee, board of control or bureau of materia medica (call it what you will), representative in character, which should have as its functions the cooperative classification and standardization of the newer materia medica, the censorship of advertising, the promotion of professional and commercial interests, and the protection of the public from dishonest commercial exploitation.

SYMPOSIUM ON DIABETES

Experience with Oatmeal in Diabetes

DR. ALFRED C. CROFTON, Chicago: v. Noorden's adoption of the oatmeal diet treatment was purely empirical, and even up to the present there is no definite knowledge as to the mode of action of this agent. Authorities differ as to its value, but there is now at command considerable evidence that it is more or less useful. I have experimented with it to a considerable extent, and have found that, if cases are properly selected, the employment of the oatmeal diet is attended with fairly good results.

Drugs Useful in the Treatment of Diabetes

DR. D. O. LEECH, Washington, D. C.: While I believe, with many others, that no drug is curative, there are a few which act as palliatives, and in some selected cases control, to a large degree, the output of sugar, render the patient fairly comfortable and prolong his life. Opium and its derivatives, notably codein sulphate, hold first place in the opinion of many practitioners, while many consider alkalies as important as opium.

Other drugs that are worthy of mention are gold and arsenic bromid, especially in combination with tryptic and amyloptic ferments, the salicylates, particularly in the case of children, calcium as a prophylactic against boils and carbuncles, potassium permanganate, potassium iodid and emul-

sions of mixed fats. In cases believed to be due to ptomain poisoning, mercuric chlorid has sometimes been used with good effect. We can expect no beneficial effects from drugs, however, without constant and careful attention to the diet.

Surgical Features Relating to the Effect of Gallstones; and the Question of Operation in the Presence of Diabetes

DR. ROBERT T. MORRIS, New York: There are two special objections to operating on individuals with diabetes: (1) The phagocytes do not properly perform their protective function; (2) repair is not carried on well, because the reparative cells are disabled. The reason for this is on account of the cells being deprived of the water essential to their activity by the hygroscopic action of the sugar in the circulation. It has been observed that when gangrene appears in a case of diabetes which has developed rapidly, the process is likely to go on. On the other hand, in a patient who has had diabetes for years, even if there has not been much reduction in the sugar, we can operate far more boldly. In cases of gallstone disease in which operation is indicated, there comes up the question of comparative danger. Is the greater danger to be apprehended from the operation or from the continuance of the condition without surgical interference? In certain cases the formation of gallstones would appear to precipitate diabetes; and so of other sources of continued irritation. Glycosuria, like cough, is a symptom, not a disease, and in cases in which there is no such evident cause, as the changes accompanying arteriosclerosis, a careful investigation should always be made for the purpose of finding out some possible peripheral cause.

The Treatment of Diabetes as an Infectious Disease

DR. ALFRED KING, Portland, Maine: By using a sterile solution of sodium citrate and chlorid to prevent coagulation, I have obtained active growing culture of the yeast fungus, *Saccharomyces cerevisiae*, from a single drop of blood taken from the aseptic finger-tip of every diabetic patient I have been able to find in the last two months. The resisting power of the diabetic to this fungus was determined by Wright's method of taking the opsonic index. The examination of sixteen patients showed three things: (1) The existence of innumerable yeast fungi in the blood of each; (2) a disturbed power of resistance to this organism; (3) that the opsonic index registers a fair indication of the general physical condition of each patient. The indications for treatment are to restore the lowered power of resistance, destroy or remove that cause, and prevent, relieve or remove the complications which may arise. The lowered resistance may be removed by the use of vaccines and the careful regulation of the diet. So far, I have been able to study the action of the vaccine treatment in but six cases, and that for less than two months, but the results would appear to be fairly satisfactory. I am aware that I have not proceeded far in my investigation, but hope that I have gone far enough to interest other investigators in the subject.

Discussion on Diabetes

DR. J. BLAKE WHITE, New York: I have seen some surprising results from guaiacal benzoate, as recommended by Piatkowski, and among the effects observed have been increased appetite and improved digestion and assimilation, with perceptible stimulation of the nerve centers.

DR. C. E. DE M. SAJOUS, Philadelphia: Division of the splanchnic, which contains the nerves going to the adrenals, has been shown to affect the sugar in the urine. Now, the adrenals are governed by the sympathetic system, and it would appear that the pituitary body is actually the center for this. I ask, therefore, that investigators shall take the adrenals into consideration, for in this way, it seems to me, we may be able to find out the secret of this disease.

DR. WILLIAM H. PORTER, New York: I have never ventured to carry out the oatmeal treatment, as I have feared that my patients would starve under it.

DR. A. CROFTAN, Chicago: I am entirely in accord with the view that diabetes is apparently due to a variety of different causes. Practically, however, it is a disorder of the carbohydrate metabolism. Too much reliance must not be placed

on the supposed efficacy of drugs, as there is no disease so fluctuating in all its manifestations. Dr. King's contribution is new and interesting, but his view of diabetes can not be accepted without further proof.

DR. R. J. MORRIS, New York: I know of no reason why there should not be a dozen causes for irritation of the floor of the fourth ventricle, such as arteriosclerosis, injury or eye-strain. As Dr. Sajous has suggested, all these causes may act by affecting the pituitary body, which he believes controls the sympathetic system.

LOUISIANA STATE MEDICAL SOCIETY

Thirtieth Annual Meeting, held at New Orleans, May 4-6, 1909

(Continued from page 1637)

The Treatment of Syphilis by Mercurial Inhalations in a Hot Room

DR. S. SCHIRO, New Orleans: The method of treating syphilis by mercurial inhalations, known also as Campailla's method, consists in mercurial fumigation combined with diaphoresis in a small heated room, properly ventilated, and having enough air capacity to allow the patient to breathe comfortably. In the forty-four patients thus treated up to the present time I have always obtained favorable results, and draw the following conclusions:

1. Mercurial inhalations in dry heat yield more rapid, immediate and constant results in treating syphilis, of any stage, than the other methods in use; hence its special indication in severe or impending cases of syphilis.
2. For the same reason of its intensity, this method confers on the syphilitic for a longer period an intermission of apparent recovery, which is a favorable condition, especially in pregnant women, who may with much more probability have a normal delivery, greatly reducing infant mortality.
3. It is preferable for the sake of the comfort of the patients, for it saves the digestive apparatus and is not so troublesome as the injections or other methods.
4. It is harmless, except in cases in which it is contraindicated by disorders in the respiratory, circulatory and renal apparatus or by old age of the patient.
5. It does not interfere with the patient's occupation and keeps him out of trouble in eluding social or family criticism.
6. It is the most efficient aid to social prophylaxis, as the syphilitic subjects, under this treatment, quickly become non-contagious, or at least much less dangerous to others.
7. Compared with the various methods in use, this method, as it is practiced to-day in the hot room, meets better the two most important points in dealing with syphilis.

The Hyperacid Stomach

DR. S. K. SIMON, New Orleans: The first hydrochloric acid secreted is neutralized in great part by the alkaline mucus present on the gastric surface. The proteid element of the food takes up the further supply, but there is always a surplus during ordinary digestion accumulating toward the end of the process. This is what causes trouble for the stomach when there is no longer a free supply of mucus present to neutralize it and to prevent irritation of the delicate gastric nerve endings. In a clinical way, therefore, hyperacidity is strictly a relative term; the actual gross percentage of hydrochloric acid in the gastric juice may vary, depending on many factors, but the secretion of each individual gland in the stomach remains constant. The acid *per se* does not cause symptoms, but when these occur there is a relative and appreciable decrease of the mucus coating to the stomach wall. The diet should be bland. Olive oil probably acts by protecting the walls of the stomach and bismuth probably acts in the same way. The drug that has given me most satisfaction in the treatment of this condition is nitrate of silver. I believe we should drop the misleading terms of "hyperchlorhydria" and "hyperacidity," and substitute the name "hyperacid stomach."

Epilepsy and Its Treatment

DR. P. E. ARCHINARD, New Orleans: Early diagnosis is the main anchor of the successful treatment, and that diagnosis rests on a suspicion that all spasmodic affections, be they general or partial, tonic or clonic, accompanied at some stage with the least loss of consciousness, is or may become epilepsy, and must be treated accordingly. This treatment we find in the

judicious employment of the bromids, especially potassium bromid.

The use of bromid in moderation can be continued indefinitely, and is much less hurtful to mental and other developments than the attacks it is given to prevent. Potassium bromid is innocuous and cheaper than any of the others. In a large practice extending over a good many years, and including an unusually large number of epileptics, I have followed the rule of giving this class of patients bromids for months, and in some instances for years, and I have felt at all times gratified at the results. I have never seen any untoward effects.

Substitution of Muscle for Tendo Achilles

DR. A. C. KING, New Orleans: E. D., male, aged 5, while wading in a filthy gutter, stepped on a broken bottle in such a way as completely to sever the right tendo Achilles, about three-quarters of an inch above its insertion into the os calcis. Under thorough aseptic precautions the ends of the divided tendon were united with No. 2 chromic gut, but suppuration followed, resulting in the destruction of about two and a half inches of the tendon. After healing had occurred an incision was made extending from the heel half way up the leg, search was carefully made for a possible fibrous reproduction which might in time give a useful foot. Nothing was found, and all efforts at approximation failed. The gastrocnemius was split on one edge, then a transverse cut was made, thus freeing enough muscle tissue to bridge over the defect. The muscle was turned down in such manner as to fill in the gap, and the lower end was sutured to the heel end of the tendon. The wound was closed without drainage, dressings and plaster were applied with the foot in extension. The final result is all that could be desired.

Appendicostomy, Appendicotomy and Appendix Transplantation

DR. RANDALL HUNT, Shreveport: Patient was a white male, married, aged 38, weight 140 pounds. Four years ago he had an attack of malaria lasting two weeks. A month later symptoms of colitis supervened of a continuous character, except when rectal irrigation was used, and immediately recurring on its abandonment. Examination of the stools showed ameba. He was operated on Feb. 18, 1909. The technic used was that described by C. B. Keetley in the *Lancet*, Jan. 2, 1909. The appendix was opened forty-eight hours after the operation. A catheter was introduced into the cecum daily, and the bowel was washed with two gallons of a warm 1 to 5,000 solution of quinin hydrochlorid. Though the bowel movements varied from four to eight in twenty-four hours prior to operation, irrigation promptly reduced this number to one movement a day. After thirty days' treatment re-examination of the feces still demonstrated the existence of amebas and the strength of the solution was increased to 1 to 1,000. Very few amebas were found, however, and as the patient has made a gain of twelve pounds in body weight it appears perfectly logical to predict a complete recovery in the near future.

OHIO STATE MEDICAL ASSOCIATION

Sixty-fourth Annual Meeting, held at Cincinnati, May 5-7, 1909

(Continued from page 1688)

Treatment of Clubfoot in Infancy

DR. ALBERT H. FREIBERG, Cincinnati: The crux of the problem lies in securing a satisfactory over-correction of the deformity by overcoming the resistance of the soft parts which holds the bones in their abnormal relationship to one another. The technic of retention in this over-corrected position is no longer a moot point, if only the before-mentioned first requisite be attained. I find, however, that there is frequent failure to realize the importance of the third requisite for accomplishing a real and therefore permanent cure, namely, that having over-corrected the deformity, mere retention in the over-corrected position will not bring about a cure, be it ever

so long maintained. There must be added the influence of function, of weight-bearing. Since this factor is not available until the tenth or twelfth month, it is unnecessary to maintain over-correction by plaster-of-paris until a period shortly before this. Over-correction can be most easily accomplished in the new-born infant. If we ignore the position of the heel, that is the element of equinus, in the untreated clubfoot, it will be found possible, by gentle and painless manipulation, to bring the forefoot into the axis of the leg, thus overcoming the adducted position of the forefoot. The forefoot and leg are now in a straight line, and can easily be held in this position by means of a simple splint and a roller bandage. It is intended that the splint shall be removed by the mother morning and evening for the purpose of rubbing and bathing, and particularly for manipulation of the foot in the manner of over-correction. Complete correction is then undertaken as close as possible to the beginning of walking. It is now no longer an infantile clubfoot, but is to be managed precisely like the clubfoot of an older child, which I do not discuss in this paper.

The Genesis of the Non-Infectious Chronic Diseases of Middle and Later Life from Early Microbic Infection

DR. J. B. BALLINGER, Bradford: On the basis of a common origin from microbic infection of the intestinal tract and modified by the kind of infection and mode of living chiefly, a class of evolutionary diseases probably exists, many of which produce changes characteristic of old age and organic disabilities which limit individual life. In this class, with others, are lithemia, various forms of rheumatism, arteriosclerosis, some cases of endocarditis, myocarditis, and chronic nephritis, apoplexy and diabetes. That intestinal infections occur early in life, even in infancy, scarcely admits of doubt. Reactions in the form of colic, jaundice, diarrhea and fever, occurring in infants but a few days old sufficiently attest this fact. Once established, infections are often permanent. This statement is not only supported by clinical facts, but has lately been strengthened by the discovery of bacillus-carriers. A degree of immunity to some bacteria evidently becomes established, but that their influence on the organism entirely disappears therewith admits of serious doubt. Disease and death are the measure of the victory of the microbic and parasitic forces of disorganization in their persistent warfare against an individual life, but it is especially when early in life an intestinal invasion has been followed by a permanent colitis and constipation, and the alimentary canal thereby converted into a bacterial culture tube, that the development of disease becomes rapid and a well-defined clinical history apparent. These fundamental principles of etiology give increased scope and definite aim to preventive medicine, and add hopefulness of further mitigation of disease and increase of longevity as the reward of continued efforts at therapeutics and sanitation.

Mind and Medicine

DR. J. S. RARDIN, Portsmouth: As the result of renewed activity recently in the field of psychic therapeutics we hear of various cults, such as christian science, the new thought, mental culture, and more recently the Emmanuel movement, and we are led to believe that the psychic factor in treatment has been neglected by the profession. It is in nervous disorders that mental treatment has its most valuable field of usefulness—the neuroses, psychasthenia, neurasthenia, hysteria, melancholia, hypochondria, mania, etc. The trend of modern civilization is to an increase of nervous disorders. Rapid transit, fierce competition in business, supremacy of great corporations, manipulation of intricate machinery, intense artificial light, all engross the nervous system, impairing its stability. Alcoholic drinks play an important part in causing nervousness, and venereal diseases and heredity are also important factors in the increase of nervous disorders. Suggestion is the basis of psychic treatment. The patient must be re-educated and the disordered mind directed in health channels. Suggestion acts through the conscious mind on the unconscious. Every dose of medicine given is more or less a suggestion, and sometimes the more valuable part of the dose.

The placebo is just as legitimate and at times more effective than potent remedies for it inspires hope and contentment of mind, without which the unconscious functions do not act properly. In the absolute confidence of the patient we hold the key to successful treatment, and without that confidence medicine loses much of its potency. Persuasion should be used and autosuggestion practiced. The tendency of the modern cults is to combine religion and medicine. I think we should be very careful of such an alliance. Tactful words of counsel and prayer will often soothe a nervous, wakeful patient into sweetest sleep.

Choked Disc, with Special Reference to Decompressing Trephining

DR. A. R. BAKER, Cleveland: Every patient with choked disc, syphilitic or otherwise, should first be treated vigorously with iodine or mercury. If not responding favorably, the question of operative interference must be seriously considered to prevent blindness. Among operative measures to be pursued are: (a) Incision of optic nerve sheath; (b) lumbar puncture; (c) decompressing operation.

Etiology of Senile Cataract

DR. CHARLES LUKENS, Toledo: The essential cause of senile cataract is disturbed nutrition of the crystalline lens. The function of the capsule is a protecting and regulating one. The nutrition of the lens is obtained by osmosis from surrounding media. If these media become so modified by certain toxins, exudates or altered composition that the lens is no longer able to get proper nutrition, this altered nutrition may produce opacity. Chorioiditis is the result of prolonged asthenopia, which may be from several causes, and probably accounts for more cases of cataract than any other one thing. The cause of many cases is obscure, and no single etiologic factor can account for all.

Report of a Case of Hodgkin's Disease with Recurrent Fever

DR. JOHN PHILLIPS, Cleveland: The patient in the case reported was admitted to Lakeside Hospital because of swelling of cervical glands. Some of the glands were removed and microscopic changes were found described by Reed and Longcope as characteristic of this disease. Under treatment with arsenic, the remaining glands became smaller and smaller and the patient was discharged, only to be readmitted one year later with marked enlargement of glands in the neck and axillæ. Under treatment with arsenic they again nearly disappeared. The patient was admitted again with the enlargement of all the superficial glands and evidences of compression from enlargement of the retroperitoneal group. The unusual condition noted, both in the record and third admission to the hospital, was the alternation periods of pyrexia and apyrexia.

KANSAS MEDICAL SOCIETY

Forty-third Annual Session, held at Emporia, May 5-7, 1909

The council and house of delegates had their first meeting Tuesday, May 4. The financial report showed that the society is on a solid financial basis. The scientific session was opened Wednesday morning at 10 a. m., with an address of welcome by Mayor John H. Glotfelter, of Emporia. A response on behalf of the society was delivered by Dr. O. J. Furst, of Peabody.

President's Address: Tuberculosis

DR. C. C. GODDARD, Leavenworth, spoke of the efforts being made to stamp out this dread disease.

Almost one whole day of the session was devoted to papers and discussions relative to some phase of tuberculosis.

Changes in Councilor Districts and By-Laws

On Friday, May 7, the house of delegates reconvened. Several amendments to the constitution and by-laws were offered. One provided for the election of twelve councilors instead of eight as the constitution now provides. This will lie over one year and be voted on at the next annual meeting.

The by-laws were amended by dividing the state into twelve councilor districts in place of eight, and according to the constitution, as only eight councilors could be elected, four deputy councilors were appointed to serve for one year. The by-laws were also amended that the council and house of delegates could hold their first meeting on the morning of the first day of the session, and further amended that the officers of the society could be elected on the second day of the session.

Election of Officers

The officers elected were mentioned in THE JOURNAL, May 15, p. 1587. Topeka was selected as the next place of meeting.

Attendance and Entertainments

The attendance at this meeting was much larger than that of last year. Everything was done by the local committee of the society for the entertainment and comfort of the visiting physicians and their wives.

On Wednesday evening a smoker was given at the Whitley Opera-House. On Thursday morning an auto ride was given to the various points of interest in the city. A reception by the ladies of Emporia was given to the visiting ladies at the Elks club room on Thursday afternoon. A banquet was given Thursday evening, about three hundred plates being laid.

Contribution to the Carroll Fund

The appeal of the American Medical Association for the relief of the widow of Major Carroll, who lost his life as a result of work done while investigating the cause of yellow fever, was presented to the society and volunteer contributions were made, to the amount of \$55.50, which was forwarded to Major M. W. Ireland, to be added to this benefit fund.

MEDICAL AND CHIRURGICAL FACULTY OF MARYLAND

One Hundred and Eleventh Annual Meeting, held in Baltimore, May 13-15, 1909

(Concluded from page 1691)

The Specific Chemotherapy of Protozoal Diseases

DR. SIMON FLENNER, New York, dealt with the new science of experimental therapeutics, i. e., the effects of remedies in diseases artificially produced; its present status and possibilities. Dr. Welch said it was a good omen that the first paper read in the new building should have been one on a scientific subject and by a noted scientist.

The Variations of Nephrotomy Incisions from the Standpoint of Anatomic Study

DR. MAX BROEDER, of Johns Hopkins Hospital: The key to the mode of operation is the embryology of the kidney. Rotation is the most important of all factors. It begins at the third week of intrauterine life, and usually reaches 100°, sometimes 130°. The position of the kidney determines the blood supply and the type of vascularization. The posterior incision into the organ is applicable in about three-fourths of all cases.

The Bacterial Content of the Feces with Experimental Observations Concerning the Effect of Various Intestinal Antiseptics

DRS. JULIUS FRIEDENWALD and J. FREDERICK LEITZ concluded their paper as follows: 1. Regulation of diet, together with the evacuation of the bowels, is the most effectual method that we have at hand for reducing the excessively high bacterial contents of the intestines. 2. Betanaphthol and bis-muth salicylate appear to be our most effectual intestinal antiseptics in normal individuals, while aspirin and ichthalbin effect slight reduction and salol gives no results whatever. 3. The results produced by intestinal antiseptics in patients suffering with gastrointestinal disturbances do not seem to be marked, whereas the best results are obtained by regulation of the diet.

The Early Diagnosis of Brain Tumors

DR. HARVEY CUSHING: Brain tumors are very frequent. They may be removed without general anesthesia, only with

a hypodermic of morphin. The brain and dura being insensible, stimulation with the electric current is very helpful in diagnosis; so is the study of the eye grounds, the ophthalmologist often having the opportunity to make the first diagnosis. Choked disc may produce sudden blindness; it is the most important of the ocular manifestations of tumors. Inversion of color fields is not pathognomonic of hysteria; it occurs frequently in tumors. Syphilitic tumors are not removable by antisyphilitic remedies, but it is well to remember there may be some relief by their use in non-syphilitic tumors. I have operated on 40 or 50 brain tumors. Many cases of brain tumor, especially in hospitals, are mistaken for hysteria, syphilis and insanity.

The Widened Scope of Psychiatry

DR. C. B. FARRAR: There are two reasons for the activity of psychiatry in Baltimore, (1) the Phipps' clinic, (2) the activity of the lunacy commission. Mystery has lingered over this subject to the present. The word *schlenstör* is still used in Germany; diseases of the mind are still diseases of the soul. Yet our mental states are subject only to the laws that apply to the body. The last of the spiritualist physicians died in 1843 and in 1845. The somatic school triumphed with the advent of Griesinger. Psychiatry is neglected in the schools, and by the boards of examiners. In 1901 Germany required examination in it of all candidates. Every physician comes in contact with mental states. There is a classification mania; real classification of mental disturbances is impossible—individualism is essential. There are as many mental diseases as patients. We have to consider the personality of the individual and the acquired symptoms.

Family Epidemic of Acute Trichiniasis

DR. JOSE L. HIRSH: This epidemic came from eating uncooked ham. There is a large popular consumption of uncooked pork and it must be recognized that meat containing trichinae can be purchased in the markets. The attack occurred in a family of 8, 5 of whom ate the diseased ham and became affected. The ham was purchased January 31 and the disease appeared between February 7 and 12. The symptoms were edema of eyelids, abdominal cramps, nausea and vomiting, constipation, muscular soreness, urticaria, high temperature, eosinophilia constant from 18 to 45 per cent. There were no chills. The urine and stools were negative.

Fagopyrismus (Buckwheat Poisoning)

DR. HARRY LEE SMITH: The affection occurs in animals, but there is no record of it in man. The case here reported was that of a white man in whom the susceptibility was first observed at the age of 9, after eating buckwheat cakes. The symptoms as observed experimentally (application of buckwheat to scarified surface, or internal use) were itching, heat, suffusion of face, conjunctivae, neck and arms, followed by desquamation, nausea, sense of tightness in chest, rapid pulse, giddiness, labored action of heart. The immediate cause of the symptoms is unknown.

Incised Wounds of Liver: Report of Case Complicated by Evisceration

DR. ALEXIUS MCGLENNAN: Such wounds are uncommon, and their mortality is high. The chief danger is hemorrhage, and the most important treatment is to check it. Best results are attained when operation is done within six hours. The patient in this case was a white man who had a saw wound of the abdomen. The stomach and colon protruded and there was severe shock. There was an incised wound extending across the abdomen seven inches. The ribs were divided and a wound in the liver was exposed; the epigastric vessels were ligated and the liver wound closed with overlapping catgut sutures just tight enough to control bleeding. Recovery followed.

Gynecology and Obstetrics in General Practice

DR. L. A. GRIFFITH spoke from the standpoint of the country physician. He laid particular stress on three points: (1)

Asepsis in labor; (2) early recognition of cancer of the uterus; (3) the importance of a better class of midwives.

DR. J. J. CARROLL added the importance of attention to the eyes of the new-born. There were 29.2 per cent. of admission of cases due to ophthalmia neonatorum at the hospital for the blind. Of these, 76.8 per cent. of the mothers were attended by midwives and the remainder by physicians, showing that not midwives alone are to blame.

Life History of Uterine Myomata

DR. THOMAS S. CULLEN: The cause of uterine myomata is still in doubt; there is no relation to the blood vessels. Position is important. There may be only pressure, but, if the myoma impinges on the mucosa, there will be hemorrhage. Torsion (in subperitoneal form) and suppuration are occasional complications. The blood supply may be derived from the omentum or bladder, or the myoma may be entirely free. It may accompany carcinoma both of body (25 cases) and cervix (18 cases). Hyaline degeneration is nearly invariable; cystic degeneration is common. Sarcoma and myoma occurred together in seventeen cases. In a large proportion there were symptoms of irritation; many were unaware of its existence. I do not think it necessary to remove myoma in all cases. When there is no discomfort, no trouble, I leave it alone, requiring the patient to report two or three times a year.

Other Papers Read and Apparatus, Etc., Exhibited

"Methods of Skin Transplanting," by Dr. J. S. Davis; "Direct Laryngoscopy" (with exhibition of instruments), by Dr. R. H. Johnston; "Responsibility of Physicians in Campaign Against Tuberculosis," by Dr. John Girawood. Dr. G. Timberlake demonstrated the *Spirochæta pallida* by dark-field illumination, and Dr. Hugh Young exhibited a number of instruments of his own invention for the removal of tumors from the bladder by the help of electric illumination.

Miscellany

Elbert Hubbard's Misstatements on Vaccination

To the Editor:—In December, 1906, Elbert Hubbard took occasion in the "Philistine" to attack the theory and practice of vaccination. I wrote to him commenting on his misstatements, but received no reply; neither did Mr. Hubbard in his journal correct them. In view of the fact that he is still writing articles in opposition to vaccination it may be well that material for refuting his assertions should be put in the hands of those members of the profession who have not paid special attention to the subject, who may nevertheless be called upon to defend vaccination against such attacks.

After two introductory paragraphs, I said:

Let me call your attention to what I regard as the errors in your article.

1. "Dr. Jenner made investigation and found that no person who had cowpox had contracted smallpox, or, more properly speaking, he could not discover that any person who had had cowpox ever had smallpox.

"It was also the belief that cross-eyed persons and hunchbacks were immune from smallpox, but Dr. Jenner says nothing about this!"—Elbert Hubbard.

COMMENT. For seventy-five years previous to the discovery of vaccination, people in England willingly had themselves inoculated with smallpox in order that they might secure the advantage of a mild attack and thus protect themselves against a severe attack of "natural smallpox," which almost every one contracted. It was believed that almost every one had to pass through an attack of smallpox in the course of his life, just as at the present time almost every one passes through an attack of measles, and statistics bore out this opinion. Therefore, your subsequent statement—in reference to Jenner's declaring that he had inoculated his cowpox

friends with genuine smallpox—that “it is much more likely that in his excess of zeal, Jenner lied than that he deliberately ran the risk of laying himself open to the charge of committing murder,” is an absolutely untrue and unwarranted statement.

2. “Professor Waterhouse, of Harvard University, vaccinated his children, and then to prove his faith took them to a house where there was smallpox. Afterward it was admitted that he (Dr. Waterhouse) only took them into the yard or past the house where the patient lay.”—Elbert Hubbard.

COMMENT. I do not know your authority for this statement. The facts are that Dr. Waterhouse after vaccinating his children, sent them into the smallpox hospital, which was under the charge of Dr. Aspinwall, who subsequently inoculated them with smallpox without effect. Apropos of inoculation, Thomas Jefferson, who was so much interested in the subject of vaccination, insisted on inoculation as a subsequent test in persons who were early vaccinated in Virginia.

3. “At the present time out of 1,200 deaths, but one is caused by smallpox. The danger of smallpox is infinitesimal where people pay proper attention to sanitation, but the risks from vaccination are considerable.”—Elbert Hubbard.

COMMENT. Before the days of vaccination, smallpox caused on an average one-thirteenth of the total number of deaths in England. The enormous difference between one death in 13 in the prevaccination period and one death in 1,200 at the present time constitutes certainly no argument against vaccination, but a pretty strong one in favor thereof. Improvement in sanitary conditions, while doubtless accountable for some decrease in smallpox, is entirely inadequate to explain the striking decline in the incidence and mortality from this disease.

It was shown before the Royal Commission of Vaccination, and the figures are unchallenged, that during a long period in England in which smallpox declined 72 per cent., the mortality from measles had fallen only 9 per cent. and the death rate from whooping-cough a little more than 1 per cent. The diminution in the mortality from scarlet fever has only become apparent at all within comparatively recent years. You write, “the conditions that breed consumption and typhoid fever are favorable to smallpox.” Your statement is untrue. Typhoid fever is caused almost exclusively by polluted water supply, and consumption is favored by conditions which lower the general health, but its transmission can not in any sense be compared with smallpox. Smallpox must be classed with measles, scarlet fever, whooping-cough, etc.—with diseases which are extremely contagious and are apt to be transmitted by the most casual contact with the person suffering therefrom. In other words, smallpox is influenced by personal infection rather than by any definite vices of sanitation.

There is almost a universal susceptibility of persons to smallpox and to measles. In the days before vaccination it was generally agreed that about 5 per cent. of the population was insusceptible to smallpox either through the air or by inoculation. My personal experience has been such that I never have seen an unvaccinated person exposed to smallpox fail to take the disease, with the exception of three infants born in the hospital of mothers suffering from smallpox. In every other case, and the figures would reach hundreds, the exposed person has contracted the disease. On the other hand, I have never seen a recently successfully vaccinated person, or one remotely vaccinated with subsequent revaccinations, fail to be protected in the presence of smallpox. During the years 1901 to 1904 we conducted in small classes 700 students of the different medical colleges in the city through the wards of our hospital. These wards were intensely infected, as at one time there were 304 patients suffering from smallpox. It was required that all students should be revaccinated whether they bore scars or not. Of this entire number but one man contracted the disease and, on examination and interrogation, it was found that he had never been successfully vaccinated and bore no mark on his arm.

In the Municipal Hospital of Philadelphia, during a period of

34 years, in which time over 9,000 cases of smallpox have been treated, we have not had a physician, a nurse, or an attendant, who had been successfully vaccinated or revaccinated prior to going on duty, contract the disease. Physicians and nurses have no such immunity against other infectious diseases as against smallpox. The deaths from smallpox of medical men (who constitute a class particularly well vaccinated) are 13 per 1,000,000 as against 73 per 1,000,000 of the general population in England. In scarlet fever, on the other hand, against which physicians have no special protection, the figures are reversed; 59 medical men per 1,000,000 die of scarlet fever as against 16 per 1,000,000 of the general population.

4. “Fully one-half of all physicians now know that vaccination is a fallacy. To-day the best doctors decline to be vaccinated.”—Elbert Hubbard.

COMMENT. How can you commit yourself in writing to such a statement? Practically all the eminent practicing physicians of this country as well as abroad are in favor of vaccination. Indeed, on no other therapeutic procedure is there such a unanimity of opinion in the profession. I do not know of the head of an infectious disease hospital anywhere in the world who is opposed to vaccination, and these men are the best qualified to form an opinion. There may be a small number of physicians in different communities who are opposed to vaccination. It is impossible, however, that such opposition should rest on proof of the non-efficacy of vaccination as a protection against smallpox.

No one familiar with the subject at the present day makes the claim that a single vaccination protects against smallpox for life, although in Jenner's time this was thought to be the case. It would be too much to expect, for one attack of smallpox does not invariably protect against a second at a later period of life. But what is claimed is that vaccination properly performed and repeated once or twice in the course of a lifetime does give an almost absolute assurance of security against the dread smallpox.

If physicians, nurses, and attendants, who are thoroughly vaccinated, can live in perfect security against this disease though coming into daily contact with cases of smallpox, it should certainly be possible for persons living under more favorable circumstances to secure to themselves a like protection. Smallpox, as you suggest, is a comparatively rare disease at the present time in vaccinated countries. The same, however, is not true of countries in which vaccination is greatly neglected. In these countries smallpox still finds its thousands of victims. According to figures collected by the German Imperial Board of Health, there were 275,502 deaths from smallpox in five years from 1893 to 1898 in the Russian Empire, including Asiatic Russia; in Spain, with a population of ten and one-half millions, there were 23,881 deaths from smallpox during this period. Hungary had 12,241 deaths and Italy and Austria 11,000 deaths each. In Germany, however, where vaccination is well carried out and where the population is five times that of Spain, the total number of deaths from smallpox during the same five years was 287, and these were largely in persons of foreign birth who had not been subjected to the vaccination laws of the country.

There is only one sane ground for opposition to vaccination, and that is, that it is not devoid of some danger. But the danger is so slight in any individual instance that it is almost a negligible quantity. No human act is completely unattended with risk. Railroad travel, attendance at the theater, the taking of an anesthetic, etc., all necessitate the taking of a slight risk. Certain it is that there is no reason why we should not be willing to take a minimal risk to secure protection against a disease which was, until the introduction of vaccination, a devastating plague. I do not deny that accidents and injuries, chiefly wound infections, occasionally complicate vaccination, but nearly the whole of these are preventable when the fullest precautions are taken in the propagation and preservation of the lymph, the operation itself, and the care of the arm after vaccination. In the conclusions of the Royal Commission on Vaccination the following is stated: “It is to be hoped that our report will stimulate belief in the efficacy of vaccination, that it will remove some

misapprehension, and reassure some who take an exaggerated view of the risk connected with the operation, as well as lead to a more ready enforcement of the law by local authorities."

I am sending you under separate cover several pamphlets which I trust you will read. Furthermore, if you are sufficiently interested in this matter, I would advise that you read the conclusions of the Royal Commission on Vaccination, a committee composed of eminent men appointed by Queen Victoria.

JAY F. SCHAMBLER, Philadelphia.

Florida Committee on Medical Education Report

At the session of the Florida Medical Association, held at Pensacola, April 7-9, the following report of the Committee on Medical Education was read by the chairman, Dr. Edward N. Liell:

The intelligent treatment of diseases requires training and experience on the part of the practitioner of medicine. A man is of value to the world, in his profession, only when his ability is such that he contributes something over and above the amount represented by his fees.

The time is at hand when it must be insisted on that the man licensed to practice medicine shall be first of all well educated; and that he shall have been thoroughly grounded in the fundamental sciences on which all medical practice depends.

Low educational standards have heretofore been not only an injustice to the public but demoralizing to the profession. The public has been slow to appreciate the fact that its interests and its safety lay in good standards of medical education. It has even been hostile at times to the reforms which the representatives of the leading medical societies have endeavored to bring about. This attitude of the public makes the practice of medicine the easiest field for the charlatan and the quack to enter.

High standards should be enforced in professional education. There should be not only legal regulation of medical licensing, but expert scrutiny of medical education and in the admission to practice.

Finally, in raising the standard of medical education, influence should be brought to bear towards securing a proper standardization of our medical schools and a just and equitable system of examining boards for the issuance of licenses to practice.

Louisiana Committee on Education Report

The Committee on Medical Education of the Louisiana State Medical Society of which Dr. L. G. LeBeuf is chairman, presented an extended report at the annual meeting of the society at New Orleans, May 4 to 6, 1909.

The growth and the standing of Tulane University Medical Department are dwelt on in the report and statistics given comparing this with other medical schools. The new buildings which at a cost of \$275,110, have been erected and the great improvement of the teaching staff are alluded to. A new surgical and gynecological department to Charity Hospital, the Delgado Memorial with 120 beds, adds to the clinical facilities of the school. The average cost of teaching each student is shown to be \$175.44, while each student contributes but \$139.75 leaving a net cost of \$35.69 for teaching each student which must be met from other sources. This school is highly commended by the committee for the progress made, but is urged to extend its course to include thirty weeks of actual work each year excluding holidays and examination week.

In regard to L'Int Medical College, while that college is commended for the adoption of higher standards and statistics are given showing its successes and failures at state board examinations it is also stated that the college was working against dreadful odds with little endowment, with practically no clinical advantages and with a most modest laboratory equipment. Under these circumstances the committee was unable to understand how the school could do as well as it was doing. Allusion was also made to the wild search for students by colored medical schools whereby students which failed at L'Int were taken without condition at other colleges.

The committee suggests that instead of the several smaller colored schools now struggling against insurmountable odds, some one or two central locations should be selected where prejudice is not so extreme and all means and energy be concentrated in building up one or two large well-equipped universities which with ample means, could obtain sufficient hospital advantages and better laboratory equipment. Medical education for colored students could then not only comply with the letter of the law but also with the requirements of modern medicine. Negro education should be encouraged in medicine as the 9,000,000 negroes of the South have a right to have physicians of their own race treat them if they so desire. But they also have the right to expect that such physicians shall have had a thorough training in high-grade medical colleges.

Connecticut Homeopathic March Report

Dr. Edwin C. M. Hall, secretary of the Connecticut Homeopathic Medical Examining Board, reports the written examination held at New Haven, March 9, 1909. The number of subjects examined in was 7, total number of questions asked, 70, percentage required to pass, 75. The total number of candidates examined was 2, both of whom passed. The following colleges were represented:

College	PASSED	Year Grad	Per Cent.
New York Homeopathic Medical College (1899)	84	(1906)	87

Medical Economics

Business Partnerships in the Medical Profession

The Chicago Physicians' Club, at its March meeting, held a symposium on business partnerships in the medical profession, three speakers taking the lead in the discussion, their subjects being "The Advantages of Business Cooperation and Business Partnerships," "Division of Fees from the Surgeon's Standpoint" and the "Equitable Arrangement of Fees from the Physician's Standpoint."

Dr. Casey A. Wood discussing the business partnership with special reference to office cooperation, advocated a combination of physicians devoting their time and energy to various specialties and forming a distinct business partnership. He attributed the rarity of such an arrangement to conservatism on the part of physicians and pointed out the fact that this kind of an arrangement is common in the legal profession. One probable obstacle in the way of such an arrangement was a lack of confidence in each other on the part of physicians, not so far as skill is concerned, but with reference to business relations.

There was nothing inherent in the study and practice of medicine that rationally explains this unnecessary and harmful distrust of each other that sometimes characterizes the members of the medical profession. The remedy lay in multiplied opportunities for better knowledge, both social and professional, of each other. Business partnerships in large centers and in small towns would greatly benefit not only the profession, but also the public, as it would increase mutual cooperation and give the public better service.

The material advantages of such partnerships, he said, were larger and better equipped offices and waiting rooms, common laboratories and libraries and better general equipment. The most obvious combination of this sort would be two internists, a general surgeon and a representative of each of the ordinary specialties. Another arrangement, which often works well, was an association of eye, ear, nose and throat specialists. The rapidly growing field of each of these departments was making it increasingly difficult for one man to cover all of them adequately. Another advantage was that many routine but necessary examinations could be made by assistants, thus saving time both to the physician and to the patient. Well-equipped laboratories and adequate libraries were easily obtained where half a dozen or more men were working together; properly equipped operating rooms, as well as competent bookkeepers, office attendants, assistants, etc., were also possible. Another advantage was the opportunity offered to each individual member of such a firm to take needed vacations and absences from work for the purpose of further study without feeling that his practice was being neglected. Any member of such a business association should have the advantage of the advice of another member at any time without extra charge to the patient, because the fee paid by the patient should give him the advantage of all the equipment, human or otherwise, in the entire office, and the charges should be sufficient to cover such a contingency in order to forestall any unfavorable criticism. The question of the division of profits should be left entirely to the members forming the partnership.

Dr. J. F. Percy, Galesburg, considered the much discussed question of division of fees. He said that the trouble with the fee-splitting proposition was that most of us were not sure when it departed from the fundamental principles of clean ethics, and that ethics of some sort were and always would be necessary to the human, civilized family. The larger part of the medical profession was opposed to such division. Those in favor of it were either willing to give or to take. Those willing to take were generally either young physicians unaware of the wrong they were committing and anxious to make as much as possible, or older practitioners who were willing to accept a part of the fee of the more successful money-getting member of the profession as a reward for collecting cases for him. Those who give were young men who wish to get the work of the specialist at the lowest possible price or specialists who had been in practice for years and whose business was not increasing. The origin of the fee-splitting custom was interesting.

Dr. Percy said that twenty-five years ago there were few surgeons and they were all in the large cities. All had immense personal followings, not only in the city, but for hundreds of miles around. These men trained assistants who went into practice for themselves and began to look for work. In order to get cases from the older men some of these younger men offered commissions to the general practitioners. After they got as much business as they wanted or could do they stopped paying commissions.

This practice, Dr. Percy thought, had been kept up by the ever-increasing number of young men who had been internes or assistants to surgeons in the city hospitals, who, seeing no chances for any returns from surgery in the city, are trying to establish themselves in the smaller towns and cities. This practice was also encouraged by so-called postgraduate schools, which gave courses in surgery and other special lines of practice. The graduates of these schools wished to acquire the position and income of specialists without devoting the time necessary to build up a clientele legitimately.

Medicolegal

Each Act by which One Practitioner Personates Another is a Separate Crime

The First Appellate Division of the Supreme Court of New York holds, in the case of *People vs. Dudenhausen*, that under Section 153 of the public health law of New York, which provides that "any person who shall practice medicine under a false or assumed name, or who shall falsely personate another practitioner of a like or different name, shall be guilty of a felony," each act by which one physician personates another constitutes a separate crime, and the commission of one crime has no relation to or bearing on the other.

As a consequence, the court further holds that when the indictment in this case charged a practicing of medicine with a particular individual on a particular date under a false name it was error to admit evidence of the defendant's relations to two other witnesses, one more than two months prior to the crime charged in the indictment, and one eight days before.

Here, the court says, the defendant was indicted for violating a particular statute, which provided that personating another practicing physician was a crime. To prove the crime it was necessary to prove that the defendant personated another practitioner, and the indictment alleged that that was what he did. To prove that he did practice medicine by prescribing for a person named in the indictment on a particular day named was not a part of a scheme the successful accomplishment of which the defendant was indicted for, but for violating the statute by doing a specific act charged in the indictment, and the intent of the defendant was not an essential element of the crime.

Justice Clarke, however, takes the ground, in a dissenting opinion, concurred in by Justice Scott, that the continued advertisement in the papers, inviting various persons to the same office for medical treatment by the same man, under the same impersonation, furnished a connection between the various occasions which permitted evidence thereof on the ground of a common intent and design; the offense charged being the fraudulent practicing of medicine.

Mental Requirements for Criminal Responsibility

The Court of Criminal Appeals of Texas says, on the appeal of *Thomas vs. State*, that the following conclusions seem to be supported by all the authorities: First, that the law does not require, as the condition on which criminal responsibility shall follow the commission of crime, the possession of one's faculties in full vigor, or a mind unimpaired by disease or infirmity; second, that the mind may be weakened by disease, or impaired, and yet the accused be criminally responsible for his acts; that he can only discharge himself from responsibility by proving that his intellect was so disordered that he did not know the nature and quality of the act he was doing, and that it was an act he ought not to do.

1. Cardiac Arrhythmias.—Satterthwaite quotes Gaskell's division of the functions of heart muscle into five classes: (1) rhythmicity; (2) excitability; (3) contractility; (4) conductivity; (5) tonicity. We have already learned enough from sphygmographic and polygraphic tracings, studied in conjunction with other objective and some subjective signs, to enable us to classify clinically, also, at least five correspond-

ing forms of arrhythmia. He refrains however, from discussing abnormalities of excitability and tonicity, because we have as yet no clinical criteria for recognizing them. After discussing the neurogenic and myogenic theories and arriving at the conclusion that the influence of the nerves on the heart must be recognized equally well with the power of the muscle fibers among the influences that govern cardiac action, Satterthwaite considers in detail pneumogastric arrhythmia (fundamental or sinus irregularity) and extrasystolic arrhythmia, as disturbances in the first class. No great importance is necessarily to be attached to mere sinus irregularity, because it is simply a variation in rhythmicity within normal bounds and functional in character, depending on a temporarily disturbed condition of the heart, or on an underlying systemic affection, or on temporary disturbance of the function of the nerves. "Extrasystolic arrhythmia" is easily recognized in a polygram as a "premature or dwarf beat" in the radial pulse, followed immediately by an abnormally long pause. It is produced by a stimulus starting in the remains of the primitive cardiac tissue in the auricle, ventricle or auriculoventricular node, independently of the sinus rhythm. The bigeminal pulse can be produced by extrasystoles, succession of which may produce the trigeminal or quadrigeminal pulses. Extrasystoles occur at all ages and under the most varying conditions both in health and in disease. Coffee and tobacco hearts and gastrointestinal reflexes are extrasystolic arrhythmias. In high temperature they indicate severe toxemia, in convalescence, a weak heart, in pneumonia or rheumatic fever cardiac complications. The subjective symptoms are (1) The feel of the extra thud in the chest and neck, or (2) the impression that the heart actually stops during the compensatory pause, (3) often giddiness. An example of disturbed contractility is the *pulsus alternans*. The astonishing regularity of its appearance should warn the physician that he is dealing with a case of alternating pulse rather than of extrasystole. The rhythm is invariably irregular. When the rate is not markedly increased patients may live for years, but when it is greatly increased, with fluttering in the chest, breathlessness, edema, cyanosis and venous fullness, the prognosis is grave. In affections of conductivity the stimulus for contraction starting in the sinus may be delayed, may not cross or may be blocked in its course through the auricle over the auriculoventricular bridge to the ventricle. This is the cause of the several varieties of heart block. Symptoms of heart block are irregularity and slow ventricular rhythm, with sometimes a sense of weakness or of exertion or dyspnea. Sir William T. Gairdner is said to have suffered from heart block, yet lived to 82. Errors in conductivity are easily made out by polygrams or may be determined by the inharmonious action of the radial or apex and jugular. There are three varieties of this form of arrhythmia, (1) partial, (2) complete, (3) the Adams Stokes syndrome. Satterthwaite discusses the treatment and urges the importance of a good polygraphic instrument for diagnosis.

2 Trembles and Milk Sickness.—Moseley endeavors to show that trembles and milk sickness in animals are due to aluminum phosphate obtained by eating the white snake root or the rayless golden rod. He shows by experiment that the pathologic appearances found in animals poisoned by these plants are indistinguishable from those caused by aluminum phosphate poisoning, further, that watery extracts of the plants do not show aluminum on testing, and are not poisonous to rabbits, while the leached leaves, dried and given to a rabbit, produce the same effect as leaves from which nothing has been extracted. The objection, therefore, that no poisonous effect was produced by the consumption of the gelatinous extract from evaporating the liquid in which the flesh of animals with trembles had been boiled, is not conclusive to the contrary, since the meat itself must be eaten to produce the effect. The meat of animals that have died of trembles will cause trembles in animals that eat it, whether raw or boiled.

- 6 •Breast Abscesses. Report of Seven Cases Treated by Bier's Suction Method. R. L. De Normandie, Boston.

- 7 •Effects of Coffee and Their Remedy. W. Wesselhoeft, Cambridge, Mass.
8 •Coffee as a Beverage: Its Use and Abuse. R. Amory, Boston.
9 Impuritate Anus. L. C. Kingman, Providence, R. I.
10 Intermittent Hydronephrosis. Report of Four Cases (concluded). D. F. Jones, Boston.

6 Breast Abscesses.—De Normandie describes the apparatus and method for applying Bier's suction, and reports in detail seven cases of abscess of the breast in which he has used it with excellent results in six cases and failure in one. He discusses each of the cases separately.

7 Coffee.—Wesselhoeft discusses the injurious effects of coffee in the light of laboratory investigations, which, he concludes, tend to show that the caffeine is the noxious constituent. He describes a preparation which, it is asserted, renders possible the extraction of the caffeine from the coffee bean, without at the same time depriving the infusion of its savor and aroma.

8 Idem.—Amory says that caffeine and tannic acid should be excluded as far as possible, from the cup of coffee, in order to avoid a deleterious effect, while as much as possible of the volatile oils should be included in it. Coffee should therefore, be taken with food and not fasting. After a full meal or during it, coffee is beneficial to digestion. When brain or muscular stimulation is desired it is better to take caffeine, for it can be accurately dosed. Hot or boiling water should be avoided in making coffee, and an infusion should be made with cold water. Amory has for the last eight years prepared his coffee in a porcelain or china vessel with cold water. It does not lose color, strength or aroma for two or three weeks if kept corked and in a cool place. The infusion is prepared in a concentrated form and, before using, water, milk or cream, heated to boiling point is added to set free the volatile oils. He describes the preparation of the cold coffee extract. He particularly objects to the use of metal utensils and hard water which contains salts.

17 Deficient Oxidation in Relation to the Etiology, Pathology, and Treatment of Nephritis (to be continued). N. E. Ditman and W. H. Welker, New York.
18 •Deafness Following Febrile Diseases, and Its Prevention. J. A. Pratt, Aurora, Ill.

16 The Individual as a Surgical Factor.—Crispin discusses the reciprocal influence of diseases and traumatism produced either accidentally or intentionally. He says that it is a dangerous error to undervalue the constitutional disturbances which underlie many surgical diseases, and a useless nicety to establish a distinction between diatheses and the lesions which they produce, it is a well known fact that wounds are dangerous in persons who are suffering from certain general diseases, such as diabetes, malaria, syphilis, general intoxications, either from internal or external sources, as those from the intestines, alcoholism, saturnism, etc., all conditions that may eventually cause alterations of the liver, heart or kidneys. Alcoholism has only to be mentioned to evoke that dreaded postoperative sequel, delirium tremens and the general alterations of the organism, for it is a truism that chronic alcoholism profoundly modifies the recuperative process. These morbid conditions have a decided influence on all surgical operations, even before the lesions which they produce become appreciable. He then discusses in detail, in the order which their gravity demands, the constitutional states which have to be corrected or eliminated if possible before attempting any surgical procedure. They are Renal insufficiency, asthma, autointoxication, hepatic insufficiency, glycosuria, cardiac insufficiency, anemia, malaria, syphilis and the mental status, particularly with reference to fear. He concludes, with an earnest plea for a more extended recognition of the heterogeneity of the individual, and a fuller appreciation of the bear-

ing of the above-mentioned constitutional conditions on the question of operative interference.

18. Deafness Following Febrile Diseases.—Pratt summarizes his paper as follows:

1. The majority of ear diseases are caused by adenoids and enlarged tonsils.
2. These conditions are in the greater proportion caused by mechanical obstructions of the Eustachian tube.
3. The germs found in the secretions are present in the normal middle ear as they are in the nasopharynx and sinuses.
4. While varying in different parts of the country, from 25 to 30 per cent., of the children have adenoids or enlarged tonsils.
5. All hypertrophied lymphatic tissues of the nasopharynx should be early and completely removed, so that mechanical obstruction of the Eustachian tube will not occur during congestion of the nasopharynx, to interfere with the drainage and ventilation of the middle ear.

- 25 Polynasal Catarrh—So-Called La Grippe. H. Hays, New York

19. Preservatives.—Greyer makes a forcible criticism on an address by Dr. R. G. Eccles on "the preservative situation" before the American meat packers' convention. He combats the contention that preservatives are necessary to keep the price of food within reach of the poor, by pointing out that they pay more now for their preserved provisions than they did years ago for non-preserved provisions, and asserts that this increase is due, not to increased cost of production or reasons of supply and demand, but to the machinations of the very men whom Eccles was addressing. The only way in which preservatives lessen the cost of production is by enabling these men to put on the market unfit contaminated products which would be rejected without preservatives. He discusses ptomain poisoning, citing passages from eminent authorities to demonstrate that ptomains are not dangerous in early putrescent stages; that most primary ptomains are destroyed by heat; that in advanced stages of putrescence ptomains are most dangerous; that secondary ptomains produced by age are not destroyed by heat; that especially dangerous ptomains have their origin in the non-putrid flesh of diseased animals; that the formation and poisonous effects of these are not prevented by preservatives; that sterility is not proof of their absence; that cleanliness, freshness and freedom from disease at time of curing or canning effectually prevents ptomains; and that days must elapse on opening a can ere dangerous ptomains can generate in such foods. He insists that water is a greater cause of typhoid than milk is, and that preservatives used in milk to kill all germ life or spores would be more fatal than the disease produced by them.

- 30 *Renal Varix. P. M. Pilcher, Brooklyn.
- 31 On Renal and Ureteral Calculi. G. Woolsey, New York.
- 32 *Procidencia Recti; Treatment by Excision. J. H. Cunningham, Boston.
- 33 *Intestinal Anastomosis by Invagination. A. E. Maylard, Glasgow, Scotland.
- 34 Excision of the Shoulder Joint. C. L. Scudder and J. D. Barney, Boston.

28. Congenital Mesenteric Cysts.—Deaver reports cases of congenital mesenteric cyst and reviews the literature of the subject. He enumerates the four ways of dealing with intramesenteric cysts: (1) by aspiration; (2) by cystostomy and drainage, with or without the use of caustics; (3) by enucleation; and (4) by resection of the involved intestinal segment. The first method is obsolete, the second is useful in the presence of numerous adhesions, the third is ideal when practicable, and the fourth he recommends in multiple juxtaposed cysts when too much surgical interference, as from

dealing with cysts one by one, carries more risk than simple resection.

30. Renal Varix.—Pilcher considers renal varix a distinct pathologic entity, being an angiomatous disease of the renal papillae, analogous to varicocele, etc. Many cases of supposed idiopathic hematuria are due to it. It may be impossible to differentiate it before operation from hematuria due to nephritis and renal papilloma. In most cases gross pathologic lesions are not found, but microscopic examination shows angiomatous disease of the papillae. Renal decapsulation and fixation of the kidney will cure cases of unilateral hematuria due to nephritis. Nephrotomy is the operation of choice, the incision being made along Broedel's line, to avoid injury to arteries. Nephrectomy is indicated only when rapid and bloodless operation is demanded, or when nephrotomy fails to relieve the hematuria.

32. Procidencia Recti.—Cunningham describes an operation which he has employed satisfactorily in dealing with prolapse of the rectum in three cases, namely, by excising the mass. He was unable to find a description of the details of procedure, though the operation is recommended, so he publishes his own technic in detail. He summarizes his cases. The results of the operations have been most satisfactory and it is a surprising fact that continence of feces has resulted.

33. Invaginating Intestinal Anastomosis.—Maylard describes in detail a simple method of anastomosing one segment of the intestinal canal within another. He illustrates it with a case of excision of the cecum. After removal of the diseased part, the proximal patent end of the ascending colon is stitched up and withdrawn enough to permit a longitudinal incision of sufficient length (determined by the size of the ileum) to be made through the parietes slightly above the occluded end. A large-eyed needle, threaded with a silk suture about 18 inches in length, is carried three or four times across the patent orifice of the ileum, as if to occlude it. The free end of the suture, left long, is passed through the eye of the needle, so that the ileum is now secured as by a sling. The needle is passed into the colon through the previously made incision, and directed up the intestinal canal for about two inches, when it is made to penetrate the bowel wall from within outward. By pulling out the needle and dragging on the sling suture, the ileum—with a little guiding—is drawn through the incisions and made to pass for a short distance along the canal of the colon. While an assistant keeps tension on the sling, the operator begins to fix the ileum to the colon by a series of interrupted Lembert sutures, passed around the circumference of the opening of the colon. The needle is unthreaded; and by pulling one end of the sling suture the other is drawn out of the ileum, the orifice of the latter being thus left free to open out. It only remains for security's sake to tie a ligature around the puncture in the colon through which the needle and suture pass. The immediate advantage claimed for this operation is a lessening of the time of execution with the consequent minimizing of the risks of shock and infection. The after-advantage is the probability that neither occlusion nor contraction will take place at the opening of the colon. Maylard discusses the future fate of the portion of bowel drawn into the canal, and mentions intussusception as a possible untoward result.

35. Diagnosis of Gastric Ulcer.—Hall has studied fifty consecutive cases of gastric, pyloric and duodenal ulcer in which the diagnosis was placed beyond all doubt by the findings at operation, expressly to bring out the relative frequency and value of the different symptoms and signs of ulcer. In brief, it was noted that pain (82 per cent.), persistent sour stomach (80 per cent.), tenderness (70 per cent.), vomiting (66 per cent.), and rigidity (60 per cent.), were the most frequent indications of ulcer. Gastric hemorrhage occurred in only 34 per cent. and bloody stools in only 8 per cent. The author's experience confirms that of the Mayos that those patients with the stomach dilated beyond all hope of regaining its motor power, generally fail to improve. There is frequently great dilatation in cases in which on operation the pylorus admits a finger freely so that mechanical obstruction can not be the sole factor. The influence of spasm of the pylorus from the irritation of an ulcer in that region possibly from hyperacidity alone in the causation of such a dilatation is most important. The frequent finding at operation of enlarged lymph nodes should be noted, as well as the chance of error in basing a diagnosis of cancer on their presence with an associated thickening about the pylorus. Hall suggests that we are inclined to look on gastric ulcer as comparatively rarer than it is, that we are too apt to look for a classical history especially of vomiting and hematemesis, with a high acidity reported from the laboratory, and that in consequence of placing too much reliance on the chemical findings and too little on the physical examination we make too many diagnoses of hyperacidity, when the finding, by careful examination of the slightest unilateral rigidity in the epigastric region associated with local tenderness, should lead us to diagnose ulcer instead. The chemical evidence is so extremely variable that we should not let it outweigh the more reliable findings of the bedside examination.

37. Typhoid Bacilluria.—Connell draws the following conclusions:

1 Typhoid bacilluria is a great menace to public health. Of all excretions containing typhoid bacilli, the most dangerous is the urine of the declining and postfebrile stage of typhoid fever. The feces are a greater public menace during the active stage of the illness but taking the course of typhoid fever as a whole, the urine is probably the great spreader of this disease. However, in chronic typhoid bacillus-carriers, the bile more frequently than the urine is the medium in which the bacteria have perpetuated themselves.

2 As a routine in every case of typhoid fever, during the decline and convalescence, the urine in the bladder should be rendered inhibitory to the growth of typhoid bacilli. Bacilluria once established should be terminated by urinary antiseptics or by irrigation of the bladder. Obstinate ulcerative cystitis should be treated by surgical drainage. The passed urine of the typhoid fever patient at all stages of the illness should be disinfected with the same care as the feces.

38. Abstracted in THE JOURNAL, Dec. 10, 1908, p. 2182.

39. Spasm of the Intercostals as a Physical Sign in Lung Disease.—Pottenger has found rigidity of the chest muscles, particularly the intercostals, a constant sign in patients suffering from pulmonary tuberculosis. Not only has he been able to map out the areas of infection, but he has been able to judge the nature of infiltration with a considerable degree of accuracy by the condition of the muscles, the rigidity being much greater over dense infiltrations than over those of less degree, and greater over recent inflammatory infiltrations than over old quiescent ones. He discusses the explanation which remains doubtful. The intercostal rigidity must not be confused with the feeling of resistance found over non-air-containing organs like the liver and heart. He demonstrates that it is a true muscle spasm not dependent on the thickness of the muscles themselves. The best method of detecting the intercostal rigidity is a systematic palpation of the intercostal spaces beginning at the lowest and comparing the rigidity of space with the one above and also with the corresponding space on the other side. In examining, the fingers should not be placed flat on the chest, but the palpation should be made with the ends of the fingers gently pressed into the intercostal spaces. In advanced cases of pulmonary tuberculosis, he has found that when the tissues break down and form a superficial cavity the resistance formerly noted disappears. This he attributes not to the diminution of rigidity, but to the lack of support previously furnished by

infiltrated tissue. He holds that this spasm of the chest muscles, besides being an important diagnostic physical sign in itself, helps to explain other well-recognized signs, such as lagging on the affected side, contraction of the chest wall, ankylosis of the costo-sternal articulation, diminution of the respiratory murmur and the harsh impaired respiratory note. So far, he has been able to detect muscle rigidity above the clavicle and the spine of the scapula, or in the first intercostal space, in every early case he has examined. The rigidity remains for a long time, even over long healed lesions. This he attributes to a fibrous degeneration. He protests against the tendency brought about by the introduction of laboratory methods to neglect physical diagnosis.

44. Adiposis Dolorosa.—Price reports two cases that came to autopsy, and discusses the subject in the light of these observations. The disease develops gradually in most cases; occasionally rapidly but never abruptly. The cardinal symptoms are (1) fatty deposit; (2) pain and tenderness on manipulation of the adipose deposits; (3) general asthenia; (4) psychic phenomena. He discusses these separately. He differs with those who disregard alcoholism and syphilis as possible etiologic factors. He summarizes the results of the 6 previously recorded autopsies and the 2 now reported, and finds the thyroid affected in 7 of the 8 cases. The hypophysis also was distinctly affected in 5 cases, and had been unexamined microscopically in at least 2 of the remaining 3 cases. It has been found that in animals when the thyroid is extirpated the pituitary body enlarges. He thinks that sufficient attention has not been given to the hypothesis, and suggests that etiologically it is almost as important as the thyroid. He suggests that the symptom group may result from a primary disease of either of those structures, the other being involved secondarily, though their close interrelations have been noted in other structures, particularly the genital organs. Recovery from adiposis dolorosa is rare, but the disease itself does not directly cause death. Complete intermissions are but remissions and are common. The treatment leaves much to be desired. The salicylates advantageously combined with bromid salts are useful to relieve pain. Aspirin is of value. Extract of the thyroid gland is the most valuable remedy at our command. The pituitary body at present has little value as the results of its use are not known. Potassium iodid is called for with a syphilitic history. The heart may require attention.

47. Mercurial Poisoning.—Carpenter and Benedict, in working with a respiration chamber in which the exit tubes were closed with mercurial valves, observed several instances of poisoning of the men experimented on in the chamber, which they attribute to the toxic action of mercurial vapor. On reference to the literature they find that Bing reports nine cases of poisoning in a hospital, due to the escape of steam through a mercury reduction valve. The patients exhibited a temporary rise of temperature, increase of pulse rate, cyanosis, vomiting and diarrhea. Two of the patients (infants) died, but the others recovered in a few days. Carpenter and Benedict give the record of nine experiments in which symptoms of poisoning were exhibited. The symptoms were usually nausea, increase of pulse rate and respiration, and in most cases rise of temperature. Attempts to demonstrate the

presence of mercury and its effects on animals were inconclusive. Some difference in susceptibility was shown, as some individuals showed no symptoms after a long stay in the respiration chamber.

53. Faradic Stimulation.—Martin has worked out a formula for the measurement of "make" shocks, and draws the following deduction: Comparison of the formula for "make" shocks with the one previously established for "break" shocks, shows that the relationship between the two sorts of stimuli depends in any given inductorium altogether on the intensity and voltage of the current through the primary coil. The effects on the relation between "break" and "make" shocks of variations in the intensity and voltage of the primary current may be stated in general terms thus: The higher the voltage of the primary current and the less its intensity, the more nearly will "make" shocks equal "break" shocks; conversely, the lower the voltage of the primary current and the greater its intensity, the more will "break" shocks exceed "make" shocks. With primary currents of high intensity and low voltage large variations in intensity produce relatively slight alterations in the stimulating values of "make" shocks.

55. Absorption of Fat.—Whitehead has endeavored to test the question as to whether fat is absorbed in emulsion or in the form of soap, by staining the fat fed to a cat with sudan III. The animal was killed and the intestinal villi and lacteals examined. It was found that while the fat in the lumen of the intestine was colored, that in the villi and lacteals was colorless. The experiment appears to show that fat is absorbed, not in the form of an emulsion, nor in the solutions of fatty acids, but in the form of a soluble soap.

- 72 *Acquired Venereal Infections in Children F. Pollack, Baltimore

72 Venereal Infections in Children.—Pollack gives a study of 187 children treated in the women's venereal department of the Johns Hopkins Hospital Dispensary. There were 54 white children of 6 years and under, as compared with 33 colored, and 63 colored over 6 years of age as compared with 33 white. The increase in acquired venereal infections in children is greater than the medical profession or the laity realizes, and the increasing frequency of the criminal infection of baby girls makes the subject a matter of grave concern. Clinically, the venereal infections in children run a milder course as regards grave complications than is the rule in the adult, but the number of complications and the duration of the disease seem almost identical. Pollack insists that the cause of most outrages on children is to be found in the superstition that a person infected with either syphilis or gonorrhea may

get rid of it by infecting another, preferably an "untouched virgin;" thus a defenseless child is a most natural victim. She believes that if one were to ask ten police officers, cab drivers, hucksters, etc., of the truth of this superstition, eight would affirm it as a "fact," and all would know of its existence, so common is it. She has been frequently requested to prepare women for maternity with the avowed intention of "having the baby take the disease away from them." She does not credit the majority of this abuse of infants to sexual perversion, for the appalling number of cases seems too large to credit to perverts. She analyzes her cases, discusses the question of temperature in gonorrhea, and the treatment of venereal diseases in children; and, further, urges the necessity of cooperation in prophylaxis with the medical profession of the school board, juvenile courts, police departments, the state attorney's office, and such charitable institutions as the Playground Associations, the Charity Organization Society and Prisoner's Aid societies.

76. Light Energy.—McIntosh, from a consideration of recorded experiments and observations, summarizes as follows the physiologic effects of light energy:

Light energy may produce an instant effect on the skin. It increases pigmentation of the skin and the energy of the sweat glands, and produces superficial hyperemia; and, as a determination of blood to the surface of the body can not take place without its withdrawal from the interior, it follows that when large areas of the body are exposed to light energy, there must be a depletion of the viscera. It exerts an inhibitory effect on bacterial growth in living tissue, a conclusion that finds confirmation in its clinical applications. It increases the elimination of carbon dioxide and the activity of the process of combustion, as well as urinary elimination; tends to raise the normal temperature and accelerate pulse and respiration, and to improve metabolism. It may produce motor excitation and reflexes. Colored rays of the spectrum may produce marked physical impressions. Blue light increases the energy and resistance of voluntary muscles, and tends to produce analgesia, frequently passing into anesthesia. The chemical frequencies exert an unfavorable influence on the exanthemata. He concludes his paper with a comparison of the efficiency of the various methods for the therapeutic employment of light energy, viz., solar energy, electric light baths, incandescent baths, concentrated energy of the sun, concentrated energy of the electric light, concentrated incandescent light energy, blue light energy, energy of red light, ultraviolet light energy, vacuum tube discharges and fluorescence.

- 80 *The Symptom Complex of Central Neuritis. I. H. Coriat, Boston

77, 79. Abstracted in THE JOURNAL, Feb 27, 1909, p. 727.

80 Central Neuritis.—Coriat summarizes 23 cases of central neuritis in which the symptom-complex of diarrhea, loss of weight, emaciation, muscular rigidity and twitching, with some fever and some changes in the reflexes, was present, 6 times in the alcoholic psychoses, 3 times in melancholia, 5 times in dementia præcox, twice in senile depression, twice in carcinoma of the uterus, 3 times in acute delirium, and once in manic-depressive insanity. He says that since the symptom complex of central neuritis is purely terminal in nature, occurring as the end-picture of certain cachectic, depressive or delirious states, recovery can not take place. On the other

hand, depressive psychoses with marked emaciation and diarrhea are frequently observed, in which neither clinically nor anatomically, can any central neuritis be demonstrated. What, then, are the conditions necessary for the production of central neuritis? A toxic etiology can easily be dismissed, as the presence of cholera and the findings in the urine are merely secondary. Furthermore, in one of Coriat's cases, a careful examination of the urine, both chemically and physiologically, failed to demonstrate any poisonous products. The change in the nerve cells can not be produced by inanition, for he has seen that under these conditions there is nothing resembling the axonal retraction. The symptom-complex can be fairly satisfactorily explained, however, by an application of Eddinger's *Ersatz-Theorie*. For the maintenance of a perfect function of the nerve cell, it is necessary that the reparative power of the cell should be accurately balanced and adjusted. If the cell becomes unable to repair the loss sustained by its functional activity, a progressive degeneration of the entire neurone follows. Mott has also pointed out how in neurones in a low state of nutritional equilibrium degeneration first begins in the fine collaterals and terminals and proceeds back to the cell of origin. Now, in certain psychoses the loss in weight, the diarrhea and the emaciation reduce the neurones to such a low state of nutrition that they absolutely destroy its reparative power. As a result, the entire neurone degenerates and the peculiar symptom complex of central neuritis follows.

- 82 *Atrophy of the Testicle C G Cumston, Boston
- 83 *The Nervous Child H L K Shaw, Albany, N Y
- 84 Cyst of the Frontal Sinus Communicating with the Frontal Lobe C F Theisen Albany

82. **Atrophy of the Testicle.**—Cumston says that when one testicle is only slightly atrophied it gives rise to very little disturbance, but when both organs are involved there is complete impotency, or at any rate generative impotency. Under certain circumstances certain psychic disturbances occur, such as loss of courage and activity, and to a certain extent, changes in character.

83. **The Nervous Child.**—Shaw discusses the effects of excessive emotionalism and says that fear is the emotion most apt to produce permanent injury in a child of neurotic temperament. Fear implies imagination, and the child who suffers most is the most imaginative. Most of the neurasthenia, hypochondriasis and hysteria, in adults, may be traced to the effects of fear in early life. Reflex irritation, from whatever source, plays an important part in the etiology of child nervousness. It occurs from the prepuce or clitoris, from gastrointestinal irritation, slow absorption of intestinal toxins, etc. Shaw describes the characteristics of the nervous child, and particularly notes the display of this characteristic in regard to food. He condemns the custom of administering medicine in food. The training of the child's nervous system can not be begun too early. The child is an imitative creature, and if the parents expect to exert proper influence they must hold themselves in check in his presence. In cases of willfulness and lack of discipline, the best results can be obtained when the child is removed from his ordinary surroundings, though it is difficult to convince the parents that this is necessary and that the mother is not the proper person to take care of this kind of case. The nervous child is the product of our present-day methods of living and the genus is rapidly increasing.

87. **Rheumatism.**—Thompson discusses the great variety of cases classed together under the term rheumatism. He particularly dwells on pressure, both inside and outside the rectum, as a factor in the causation of sciatica, and cites instances in which relief immediately followed a discontinuance of the habit of carrying heavy things, books, etc., in the hip pocket.

89. Abstracted in THE JOURNAL, 1908, p 250

92. **The Toxemia of Pregnancy.**—Myers summarizes his paper as follows

- 1 There is a special toxemia of pregnancy, but the exact nature of the toxic substance or substances is not known
- 2 The theory is tenable, that it may be due to some vice of placental synovial tissue
- 3 The pathologic changes are, primarily, necrosis of the periphery of the liver lobules in eclampsia, with secondary changes in the kidneys and brain while in pernicious vomiting the necrosis is more marked in the center of the lobules as an acute atrophy of the liver
- 4 Laboratory findings are of value in determining the question of treatment or termination of pregnancy, and the quantitative analysis of the nitrogen output is more important than searching for casts or albumin
- 5 In eclampsia with soft, dilated cervix, empty the uterus at once. With rigid undilated cervix, be governed by the clinical picture in each case. If critical, forcibly dilate and empty the uterus or under strict asepsis, perform Cesarean section
- 6 In pernicious vomiting the time to terminate pregnancy must be determined by the laboratory analysis if available by the progressive emaciation and the first indication of exhaustion fever

Myers concludes that while careful analysis is an important aid, still such examinations have the value only of all laboratory reports, and any decision as to therapeutic measures or the termination of pregnancy must be based on the condition of the individual patient. And, while we should never be eager to do this, we must keep in mind the possible necessity of terminating pregnancy.

105. Abstracted in THE JOURNAL, March 13, 1909, p. 916, and published in the *Chicago Medical Recorder*, March, 1909

108. **The Scope of Psychotherapy.**—Gadler says that while it is well known that the objective signs of any disease are directly proportionate to the intensity or extent of the morbid lesion or process, the subjective symptoms often seem to be more capricious in their degree. They vary with the individuality or even with the temper of the patient. The intensity of the pain and of other disagreeable sensations pro-

duced by a disturbance is increased by the concentration of attention, and conversely diminished by diversion of the attention. The query whether the mind can influence the actual course of lesions, as well as the subjective symptoms produced by them, is a difficult one to answer. As a rule, the cases quoted by older writers and the bulk of the illustrations mentioned by the laity can not stand the test of rigid criticism. Closer inquiry generally shows that subjective improvement was mistaken for objective changes. Indeed, it would be difficult to find the record of a case in which the direct influence of the mind on the course of any morbid lesion had been observed beyond doubt. It is easy enough to demonstrate the effect of emotions, of mental activity or mental fatigue on the circulation, the respiration and some secretions; in fact, on any process controlled directly by the nervous system. But it has yet to be shown that mental processes can in any way influence the phenomena of growth, of nutrition or of tissue change. Yet it seems reasonable to admit that the state of the patient's mind may directly influence the struggle with certain chronic diseases, especially those the course of which depends somewhat on the state of nutrition, as, for instance, slow tuberculosis. With confidence and hope a patient is much more apt to avail himself properly of all hygienic advantages and to utilize them to a better extent than when in a despondent frame of mind.

120 Treatment of Tuberculosis by Tuberculin. R. B. Underwood.

119. Spirillosis of the Lung.—Johnson records what he believes to be the first reported case of spirochetal infection of the lung. It occurred in a negro woman of 35, who had been feeling ill for a week before she had a hard chill followed by temperature of 106 F., pulse 110 and respirations 24. There was constant severe pain in the right side in the axillary line. Chest sounds were normal, except a few crepitant and subcrepitant râles. The lungs dilated evenly, there was slightly more fremitus and a duller note was heard on the right side posteriorly, and the breath and voice sounds were more distinct. The blood showed a sharp leucocytosis, but no malaria. The urine was loaded with albumen. The sputum, when stained for tubercle bacilli, showed none, but in every field there were numerous spirilla from one and a quarter to one and a half times the width of a red blood corpuscle, very thin and wavy. They stained blue, like the cocci, but not so dark. They also stained easily with a saturated solution of methylene blue, Loeffler's solution and the Wright blood stain. Johnson describes the course of the disease, which was severe, resolution setting in by crisis, with final recovery. The treatment was entirely symptomatic. He has seen two other cases, but reports this one only, as it was under observation from the initial chill. The case resembles relapsing fever, but no spirilla were found in the blood, while they were numerous in the sputum. The special complications of relapsing fever are bronchitis and pneumonia. He suggests a further search for this affection.

150 Diffuse Suppurative Peritonitis—The Fowler-Murphy Treatment. A. M. Burt, Elkins.

146. Gastric Ulcer.—Jones reports a few out of 66 consecutive cases of gastric ulcer treated during the last four years with the following results: Males, 19; females, 47; history of hematemesis, 11; hemorrhage during treatment, 3; rest cure, 51; ambulatory treatment, 15; recovery, 50; improved, 16; or approximately 75 per cent. and 25 per cent., respectively; no deaths. He controverts the modern tendency to advise gastroenterostomy as a routine measure in uncomplicated gastric ulcer. He considers that surgical interference of any kind has no place in the treatment of uncomplicated gastric ulcer. He has followed cases in which gastroenterostomy has been done and believes that the complications which may be charged entirely to the operative interference are far greater than those which naturally arise in cases of gastric ulcer undergoing a rational medical or dietary treatment. He appeals to the universally satisfactory results of medical treatment obtained by Von Leube and others in support of this position.

- 151 *Stenosis of the Pylorus in Infancy. C. L. Scudder, Boston.
152 *The Hygienic Element in the Treatment of Osseous Tuberculosis. C. F. Painter, Boston.
153 Conduct of Difficult and Abnormal Presentations. H. C. Johnson, St. Paul.

151. Stenosis of the Pylorus.—Scudder gives a general consideration of this subject, both from the literature and his own personal observations. He briefly records 12 cases, 5 of his own, and 7 from the literature, in each of which a posterior gastrojejunostomy was done, with the result that the babies recovered from the starvation caused by obstruction, increased properly in weight, are normal in height, and have maintained good health. These clinical observations appear to Scudder to demonstrate, that in children with a benign stenosis of the pylorus and otherwise without disease, gastrojejunostomy does not interfere with nutrition or with physiologic or anatomic development. Is it conceivable, he asks, that these children could live for years and develop into strong healthy individuals if the operation seriously interfered with metabolism?

152. **Ossseous Tuberculosis.**—Painter bases his paper on the observations of a series of cases, admitted to the institution where they were studied for the express purpose of trying the effect of hygienic treatment exclusively, or as nearly so as seemed safe. Some of the patients were well advanced in the disease on admission. The figures offered by Painter go to emphasize the fact that tuberculous osseous foci situated elsewhere in the body are frequently complicated by lesions in the internal organs, and, whether the association be that of cause or effect, the consequences to the patient are those of a constitutional disease. Constitutional treatment, therefore, should play an important part in the management of tuberculous lesions, the most conspicuous manifestations of which may be in the osseous system. A readjustment of the values given to different features of treatment now in use is required. While a certain amount of apparatus is unquestionably necessary and desirable, its employment in the treatment of joint lesions should be so regulated that a minimal amount of such impairment of function may result, and it should be employed only so long as the patient requires the protection of the splint to avoid pain, prevent incorrecible deformity, or lessen the likelihood of suppuration.

156 Nasal Stenosis. D. A. Atkinson, Dallas.
157 Treatment of Tuberculous Joints from the Standpoint of the General Practitioner. G. E. Adams, Fort Worth.

154. **Retrodiscalplacement of Uterus.**—Keiller studies this subject from an anatomic standpoint. He calls special attention to the uterosacral ligament, and to the reflexion of the peritoneum from the side of the cervix to the side of the rectum, termed the rectouterine fold. He points out that in addition to the sheet of peritoneum there is a deeper fibrous sheet which passes from the sacrum in the region of the anterior sacral foramina to the vagina and cervix uteri, of which he has found no description. Its function appears to be to carry branches of the hypogastric plexus of the sympathetic and the third and fourth sacral nerves to the cervix uteri and the vagina. In some cases its uterine attachment receives a muscular band from the cervix uteri. Keiller regards this sheet of fascia as the main constituent of the uterosacral ligament and an important, if not the main support of the cervix uteri, and posterolateral fornix vaginae. Repeated examinations to determine the cause of the prominent ridge in the peritoneum called the uterorectal fold has invariably shown it to be due to the fourth sacral nerve and vaginal branches of the internal iliac vessel. The man who shortens that fold by stitches, by either vaginal or abdominal route does so at great risk of including the visceral branches of the fourth sacral nerve or of wounding important blood vessels.

164. **Cancer of the Uterus.**—Everitt gives a brief historical review of the operative treatment and refers to the work of the committee of the American Medical Association. But she adds that any mention of the question of operability leads us at once into confusion, for undoubtedly to-day many mis-

take the possibility of operation at any hazard for highly probable operative cure. A considerable step will have been taken toward the desired eradication from the popular mind of the idea that cancer is an incurable disease when operators can be restrained from undertaking unwarranted procedures in extensive cases, whereby the mortality and morbidity of cancer operations are greatly increased, and some of our most valuable measures are brought consequently into disrepute. A notable proportion of the difficulties encountered in operating for cancer of the uterus are due to attempts to enucleate embedded ureters, to separate adherent bladder or bowel, or to excise involved portions of these viscera. One can hardly contemplate with any degree of patience the extensive mutilating operations falsely undertaken in the name of medical science, since a little application of the golden rule would forbid the inevitable making of the last state of the women worse than the first.

177 Pathology and Treatment of Gonorrhea in the Female. E. C. de Moss, Nashville.
178 Operative Relief of Intestinal Obstruction. F. G. DuBose, Selma, Ala.

168. **Rectovaginal Fistula and Fistula-in-Ano.**—Noble reports two simple operations, the first for the relief of rectovaginal fistula, in the lower end of the vagina when the sphincter muscle and perineum are intact; the second for excision of a fistula-in-ano without cutting the sphincter muscle. Use is made of the principle, presented by the author some years ago, of making a flap of the anterior wall of the rectum and drawing it externally to the anus in cases of complete laceration of the perineum. Both operations have proved successful in the author's hands. The article is illustrated.

170. **Diagnosis of Tuberculosis.**—Oughterson discusses detection of bacilli in the sputum and the various now well-known reactions to tuberculin.

171. **Epidemic Cerebrospinal Meningitis.**—McCabe, seeing that tuberculous meningitis is the one with which the diagnosis of epidemic cerebrospinal meningitis is liable to be confounded, makes the following differentiation:

1. In the epidemic form the onset is sudden, while in the tuberculous type it is slow.
2. Temperature, eyes, and pulse are about the same in each disease. The temperature in the tuberculous variety may correspond more nearly to the tuberculous type of fever.
3. Neck symptoms, Kernig's sign; spasm of the extremities and paralysis, are more marked in the epidemic form.
4. Cerebral pressure, as shown by the fontanelles, is more marked in the epidemic type.
5. There is a high leucocyte count in the epidemic type, while there is a low count in the tuberculous variety.
6. We have the history of an epidemic variety, and a history of tuberculosis in the tuberculous form.
7. In the epidemic variety the cerebrospinal fluid is turbid and contains polymorphonuclear leucocytes in excess, and the meningococcus. In the tuberculous type the fluid is clear and contains lymphocytes in excess and the tubercle bacilli.

172. **Transfusion of Blood.**—Cole reports a case of pellagra successfully treated by transfusion. He gives a historical résumé of the subject, describes the present technic of arterio-venous transfusion, discusses the contraindications, their detection and avoidance, the method of cell protection, and deduces indications for transfusion in the extracellular and endotoxic groups of diseases, respectively.

174. **Vesicouterine Fistula.**—Hill reports the case of a woman who, one hour after completion of labor (which had lasted eighteen hours, a fully developed child with normal presentation being born dead), felt an intense desire to

urinate, which was followed by a tremendous gush of water from the vagina. From this time on, the urine passed continually and entirely through the cervix uteri. Vesicouterine fistula was diagnosed. Hill saw her six weeks later. Through a T-shaped incision in front of the cervix uteri, he closed with catgut suture the openings in front of the bladder and uterus, which were about the size of the end of the index finger. Union was perfect, but from the continuation of the urinary incontinence, the vesical and urethral sphincters lost their function. She returned home, but returned about six months later in the same condition, but with a three months' pregnancy to complicate matters. The following technic, which, so far as Hill knows, is original, was used: With a metal sound in the urethra as a guide, a median incision was made through the vaginal mucosa from a point one inch on the bladder wall to the meatus urinarius, and then around this orifice. The mucosa was dissected from the underlying structures to the extent of an inch or more, transverse measurement. The sound in the urethra was then changed for one of smaller size. Commencing at the bladder end of the denudation, the muscular structures were folded in or brought together with a continuous catgut suture passed transversely, but never deep enough to include the vesical or urethral mucosa. As the gut was made taut after each passage of the needle, the sound was drawn from its grasp. The vaginal mucosa was next trimmed and made to fit snugly over the underlying tissue and held in position with silkworm-gut sutures, some of which were carried through the muscular tissues, reinforcing the catgut sutures. The patient was catheterized with a small soft rubber catheter every four or six hours. Hill is opposed to leaving an instrument in the urethra after this operation, and suggests the advisability of establishing vesico-vaginal or even suprapubic drainage in order not to disturb the parts until firm union is established. The extent of the dissection is to be regulated by the condition found in the individual case. Furthermore, if any one part of the muscular wall—for instance, either of the sphincter muscles—appears more injured than the rest, a special suture of catgut should be used to repair it.

- 9 Fatal Case of Lead Poisoning Due to Diachylon. F. S. Heaney.

1. **National Degeneration.**—Coates discusses the question of national physical deterioration and insists on the duty of the medical profession to take part in arresting it. He urges increased power to education authorities for systematic inspection of school children, and cooperation between the medical profession and educationists. He discusses the value of judicious physical exercise and the provision of public playing fields, the diminishing birth rate and marriage, and urges the taxing of every bachelor over 30, and the giving of privileges for healthy families. He reviews the effect of mentally defective children on race decay and also that of overcrowding and housing and the planning of towns. He urges support of the various health societies that aim to improve the condition of the people and cites Sweden as demonstrating what can be done by a national effort to check race degeneration. He discusses the evil effects of impurity on stamina and the effect of venereal disease on the decay of the race, and in this regard urges a better equipping of young practitioners to grapple with the difficult and interesting problems connected

with these complaints. Finally he discusses the effect of universal military service on the stamina of the race, and insists on the immense advantage that would accrue if a system of universal military training were enforced. Coates has watched over and over again the effect on recruits of their first three months' service; it has been marvelous. The lank, ungainly, casual, ill-developed loafer becomes an alert, strong, intelligent, orderly, self-respecting man.

4. **Nephropexy.**—Billington summarizes his paper—in which he discusses three groups of movable kidney, the predominant symptom in which is respectively local pain, digestive trouble, or spinal and cerebral neurasthenia—as follows:

1. Nephropexy is a safe and satisfactory surgical procedure.
2. Renal mobility alone is not an indication for operation.
3. Local pains of sufficient severity to diminish working efficiency are an indication for operation.
4. Chronic functional disturbance of the digestive system may be caused by movable kidney. Such cases often resist all kinds of general and medicinal treatment, and are greatly benefited by nephropexy.
5. Nephropexy is indicated in progressive spinal and cerebral neurasthenia occurring in association with movable kidney, when other measures have failed to cure or improvement is followed by rapid relapse.
6. Nephropexy is indicated when movable kidney is associated with insanity.

8. **Continuous Suction in Surgery.**—Herring advocates the use of continuous suction as opposed to intermittent aspiration, as a means of removing blood during operation and of subsequently draining wounds and withdrawing secretions, especially after cystotomy. He describes a portable apparatus which can be used in any place, and will easily maintain a continuous negative pressure without much attention.

11. **Tumors of the Large Intestine.**—Barker says that the tumors with which we have to contend in the large intestine are almost invariably columnar epitheliomata of varying degrees of malignancy, slow growing, as a rule, and with but a moderate tendency to invade the lymphatic glands or generalize in other parts of the system. The whole question of safe removal of such masses is influenced more by the presence or absence of associated obstruction than by anything else. If there is but little or no obstruction to the passage of feces through the affected part, the removal of a segment of the bowel is, to a large extent, merely a question of skill and accuracy of technic. But if obstruction is present great judgment is necessary as to whether we shall first relieve the overloaded gut by making an artificial anus for a few weeks' preliminary drainage, or at once proceed to remove the tumor and unite the divided ends. The first course is usually best, on account of the technical difficulty of dealing with a bowel greatly distended with feces above a constriction of the danger of soiling the peritoneum and wound, the difficulty of suturing after excision—which may sometimes be avoided by lateral anastomosis—and the danger of giving way of the stitches, owing to the paralyzed and sodden conditions of the bowel, proximal to a bad obstruction. It is a better and safer rule to make a provisional drain opening in the upper bowel and allow the gut to recover in a couple of weeks before attempting a junction. A careful study of the history and course of each case, and close examination of the abdomen to determine whether or not the bowel is likely to be loaded with liquid feces, should precede any operative undertaking. Barker condemns the preoperative administration of purgatives in cases low down, but considers enemata, repeated as often as necessary, desirable—not, however, just before operation. He then describes cases to illustrate his technic under varying conditions. He discusses the comparative merits of

the dorsal methods, Kraske's operation, and the combined method.

12. Operation for Enlarged Prostate.—Freyer analyzes his statistics in 600 cases of his operation for total enucleation of the prostate, in patients varying between 48 and 89 years with an average age of 68½ years. The majority had been entirely dependent on the catheter for very many years. Nearly all were broken in health, most of them subjects of grave complications, many apparently dying. In the 600 cases there were 37 deaths, in periods ranging from 6 hours to 37 days after the operation, or a mortality of 6.15 per cent. The mortality has been steadily decreasing from 10 per cent. in the first 100 cases to 4 per cent. in the last. The causes of death were uremic symptoms due to chronic kidney disease, 16; heart failure, 6; septicemia, 2; shock, 3; exhaustion (kidneys much diseased), 1; mania (hereditary in 1), 2; malignant disease of liver, 2; heat stroke, 1; pneumonia, 1; acute bronchitis, 1; pulmonary embolism, 1; and cerebral hemorrhage with paralysis, 1. Though all these deaths are accepted in connection with the operation, in not more than half the number can the fatal result be attributed thereto, the remaining deaths being due to disease incident to old age and unconnected with the operation. In 108 cases vesical calculi were removed at the same time, but all the deaths in these cases are accepted in connection with the prostatectomy, none being put down to the suprapubic lithotomy involved. Freyer reports on his first two patients, now aged, respectively, 75 and 79 years, over 8 years having elapsed since the operation. Their sufferings were severe, their life entirely dependent on the catheter prior to operation. Since operation no instrument of any kind has been employed, there is perfect freedom from urinary symptoms, they are in excellent health, and sexual power has been regained.

April

- 26 *Pathology of the Red Degeneration of Uterine Myomata. J. L. Smith, and W. F. Shaw.
- 27 *Menstruation and Menorrhagia. F. E. Willey.

26. Red Degeneration of Uterine Myomata.—Smith and Shaw arrive at the following conclusions, on the basis of three cases by A. Donald, one by W. K. Walls, and one by A. W. Lea:

1. The chief change in "red degeneration" of fibroids consists in thrombosis of the bloodvessels.
2. This thrombosis and red coloration may commence at the periphery of the tumor.
3. The tumors are also in a state of degeneration as evidenced by a homogeneous material separating the muscle bundles in many places.
4. The tumors contain fat and fat crystals, probably derived from the breaking up of the muscle bundles.
5. The tumors are liable to become infected by septic organisms and so to give rise to acute toxic symptoms.
6. Pregnancy is probably a predisposing factor in the causation of this condition.

27. Menstruation and Menorrhagia.—Willey says that we may still regard the monthly cycle as a preparation of the uterus for the development of an impregnated ovum, but we must realize that the important physiologic requirement is an efficient blood supply to the uterine musculature. Three points are important: 1. Many capillary fissures are closed during the intermenstrual period and become filled with blood and act as part of the general vascular system during menstruation and pregnancy. 2. The uterus increases in size during menstruation. 3. Besides contractility, uterine muscle possesses great possibility of hypertrophy. The monthly cycle is a vasomotor change of uncertain origin, but dependent on ovarian integrity, whereby the uterine wall is richly supplied with blood in preparation for hypertrophy in presence of an impregnated ovum. When no pregnancy occurs the increased blood supply escapes by rupture of capillaries and diapedesis of corpuscle, with possibly some slight destruction of surface epithelium. If this view of menstruation is true the endometrium plays a passive and secondary part at the monthly cycle, and menorrhagia should direct attention to the blood supply of the muscular wall, rather than to the endometrium. Various observations in reference to causation of congestion of the uterus and inefficient action of uterine muscle which lend support to this view are discussed. From these considerations Willey concludes that in menorrhagia without physical signs the aim should be (1) to relieve undue congestion—pessary or operation for misplacement, treatment of constipation and general conditions, etc.; (2) to eliminate sources of poison to the uterine muscle—lead or phosphorus poisoning, alcoholism, etc.; (3) to improve the general muscular tone of the patient by regular hours, simple nutritious food, gradually increasing outdoor exercise, Swedish movements, etc.—exercises of the arms and upper part of the body are often useful to relieve uterine congestion; (4) to assist the action of uterine muscle directly by suitable drugs, e. g., hydrastis or the cotarnin salts. Massage to the uterus, she considers harmful by directing attention to the pelvic organs. Curetting is indicated in many cases for diagnostic purposes.

Quarterly Journal of Medicine, London

April

- 28 Bronchiolectasis in Children. E. Leach.
- 29 Vasodilators in High Blood Pressure. E. Matthew.
- 30 *Etiology of Endemic Goiter. R. McCarrison.
- 31 Infective Endocarditis. T. J. Horder.
- 32 Acidosis. E. I. Spriggs.

30. Goiter.—McCarrison reports experimental investigations as follows:

1. The experimental administration to man of suspended matter, separated by infiltration from goiter-producing waters.
2. The experimental administration to man of boiled suspended matter, separated by filtration from goiter-producing waters.
3. The administration to goitrous individuals of intestinal antiseptics, notably thymol.
4. Experiments on monkeys to test the possibility of the spread of the disease by the feces of sufferers from it.
5. The microscopic examination of the feces of goitrous individuals.

McCarrison sums up the results of his researches in the following terms:

1. Goiter can be experimentally produced in man by the administration of the matter in suspension separated by infiltration from waters which are known to be goiter producing.
2. Goiter can not be so produced when the suspended matter is boiled.
3. The disease is due, therefore, not to the mineral but to the living component of the suspended matter, in other words to a living organism of disease.
4. The incubation period of experimentally produced goiter is from thirteen to fifteen days.
5. Goiter can be cured by the administration of intestinal antiseptics. It is probable, therefore, that the organism which is the cause of the disease is parasitic in the human intestine.
6. The feces of most cases of goiter in Gilgit show a plentiful amebic infection, but whether the disease is due to this infection has not been determined.

Glasgow Medical Journal

April

- 33 Recent Researches on Immunity, Especially in Relation to Diagnosis and Treatment. R. Muir.
- 34 *Cerebral Physiology and the Education of Abnormal Children (concluded). J. K. Love.

34. Education of Abnormal Children.—Love discusses the cases of Laura Bridgman and Helen Keller and gives a short

study of aphasia with the related conditions of word deafness and word blindness, which not only helps to the understanding of the mechanism of speech, but throws light on the management of a small class of extremely difficult, but also extremely important cases among backward children, as well as helping in the understanding of the difficulties of the deaf and blind. Love lays down the following general principles:

1. It is useless hammering along a ruined tract or along a sound tract toward a ruined center, in the hope of imparting knowledge to a really deaf and blind child. It is better to use a circuitous, though less used route.
2. When the remains of sight and hearing are considerable—when in the deaf they serve for the discovery of vowels, consonants, and words; in the blind, for what under favorable conditions of light, etc., is written on a book or a blackboard—these should be used to the utmost.
3. When a circuitous route is necessary, education should be directed so that Broca's center, the hereditary center for the memory of spoken words, is used.
4. When a boy is clever with his hands and good in his games, when the difficulty is chiefly with his acquisition of language, word-deafness and word-blindness should be sought for.
5. In the teaching of the aphasic child who is not mentally deficient, Broca's convolution on the right side, unless the defect is bilateral, may be made to take up the work of the hereditary speech center of the left side. When failure shows that the defect is probably bilateral, education may proceed by the help of writing, and the manual alphabet.
6. Mentally deficient children offer a different problem of the educator. The great need of the moment is to recognize their limitations.

Having due regard to physiologic indications present, the teacher should be left as free as possible in selecting the method and ordering the education of the abnormal child. The author, however, lays down the following physiologic indications with regard to the education of the orally taught deaf:

- (a) As signs are used very extensively in the education of the hearing child—during his first and second years of life—there is no physiologic reason for suppressing them at the beginning of the school education of the deaf child. They should be used just as they are with hearing children, and excluded, as in the case of the latter, as soon as the more accurate equivalent has been learnt.
- (b) During the early years of school life the acquisition of articulate speech should be the chief business of the deaf child. As soon as may be, a vocabulary of common words should be so thoroughly learnt that its use in speech becomes automatic.
- (c) In the education of the deaf, drawing should follow speech and precede writing.
- (d) Until speech has become automatic no finger-spelling should be known to a deaf child. A combined method, in which the combination is that of finger-spelling and speech is, from the physiologic standpoint, to be condemned.
- (e) The difficulty of procuring automatic speech in the deaf-born, while necessarily limiting the use of speech by these children, does not mean that it is not worth while teaching them speech.

Archives des Maladies du Cœur, Etc., Paris

April, II, No. 4, pp. 193-256

- 35 *Reactions on the Part of the Vessels: The Ice Test. (Réactions vasculaires: L'épreuve de la glace.) O. Josué and H. Paillard.
- 36 *Broncho-esophagoscopy in Diagnosis of Aneurism of the Aorta. Guisez.
- 37 *Gastric Cancer and Pernicious Anemia. A. Clerc and Gy.

35. Ice Test for Vascular Reactions.—Josué and Paillard have been seeking a test for reactions on the part of the vessels less fatiguing than the tests by severe muscular exertion or extensive application of heat or cold, and claim that their new ice test is a simple and reliable means for ascertaining the functional capacity of the blood vessels. It consists merely in the application of a piece of ice to the bend of the elbow; the patient is reclining with the arm exposed and the palm up, and all the muscles of the arm relaxed. Every two minutes the pulse is counted for a quarter of a minute, after which the arterial pressure is recorded with a mercury sphygmomanometer (the modified Potain apparatus). The pulse and arterial tension are thus recorded three times in turn at intervals of two minutes. After an interval of another two minutes the ice is then placed in the bend of the elbow. The pulse and tension are recorded again the moment the ice is applied and again after two, four and six minutes. After two more minutes the ice is removed, the skin wiped and the pulse and tension are recorded again after two, four and six minutes. The ice must not exert pressure on the arm, which would interfere with the circulation, but must be held. Among 100 persons to whom this test was applied it was easy to distinguish the arteriosclerotics and the tuberculous, as in them the reaction always differed so decidedly from normal. With normal conditions in the arterial

system the arterial pressure adapts itself to the influence of the ice and there is no modification in the pressure, but the pulse varies, or the pressure may vary and also the pulse, but always according to Marey's law; namely, that the pulse grows slow as the pressure increases and faster as the pressure diminishes. In case of functional incapacity on the part of the vessels the pulse does not vary, but the pressure fluctuates, or both fluctuate contrary to the Marey law. This abnormal reaction occurs frequently in arteriosclerosis, especially with involvement of the aorta. The same abnormal reaction occurs also in tuberculosis, but with the difference that the pressure declines progressively during and after the application of the ice, while in arteriosclerosis the pulse remains stable, while the pressure drops, but the latter rises again as the ice is removed. Among the practical points learned by this test is that arteriosclerotic patients presenting normal curves with the ice test have a more favorable prognosis. The test also throws light on the mechanism and action of digitalis in heart disease amenable to digitalis. The ice test further refutes the common assumption that the arterial pressure keeps at a constant level in the individual; on the contrary it is liable to vary within wide limits even from mere emotions. This shows the necessity for caution in ascribing to the effects of treatment any reduction in the pressure observed afterward. Twenty-five typical curves are given to show the reaction in various conditions. One curve shows remarkable fluctuations in the pulse, while the pressure was practically stable; this subject was a healthy girl of 18, very emotional.

36. Bronchoesophagoscopy in Diagnosis of Aneurism of the Aorta.—Guisez gives a number of illustrations to show how an otherwise latent aneurism may compress the trachea and esophagus and induce disturbances, the cause of which can be revealed only by direct visual inspection, disclosing the bulging of the wall into the lumen from the encroachment of the aneurism. He also reports the details of eight cases in which this syndrome was observed, and warns that aneurism of the aorta should be suspected whenever no other cause can be discovered for respiratory or esophageal disturbances.

37. Gastric Cancer and Pernicious Anemia.—Clerc and Gy give over two pages of bibliographic references on the subject of progressive pernicious anemia secondary to cancer, and warn that the presence of the cancer may be unsuspected and the whole syndrome referred to idiopathic progressive pernicious anemia, when in fact the anemia is secondary to an otherwise latent cancer. Neither examination of the blood nor the clinical symptoms nor the theoretical bases distinguish the anemia in these cases from idiopathic, progressive anemia. The latter, they say, is losing ground constantly as a morbid entity, while gaining more and more ground as a syndrome, whether the hemolysis results from the action of a cancer, the bothriocephalus, lead or other poisoning or infection. In the cases secondary to cancer the patients on record have been between 35 and 50, generally men, and the symptoms were those of progressive anemia with nothing to suggest cancer except possibly continuous, occult hemorrhages in the digestive tract. This symptom was pronounced in a personal case recently encountered.

40. Goiter in the New-Born.—Thévenot has found a number of cases of goiter in the new-born on record in the last few years, and here discusses the symptoms liable to be observed. When the enlargement is simple congestion it is liable to disappear within twenty-four hours or may appear intermittently and recurring attacks of dyspnea may be observed. The head of the child should be drawn back to examine the thyroid region for possible goiter in every case of dyspnea in

an infant. In the mild congestions, hot baths, revulsion to the legs, purgatives and ice to the thyroid region may aid in reducing the congestion, supplemented by potassium iodid and the ordinary measures for goiter. Guillermin reported last year that he shelled out of their nests the lobes of the thyroid with his fingers in one case, as for exothyropexy, and thus relieved the dyspnea without the necessity for an operation. If operative treatment is required exothyropexy is the preferable technic, possibly supplemented by an incision in the isthmus to hasten subsidence of the congestion. Pregnant women with goiter should be treated energetically to prevent congenital development of goiter in the fetus. Schmidt began at the fourth month to give iodine treatment to a pregnant woman who had already lost two children from congenital goiter. The mother's goiter diminished and the child was born free from goiter.

45 *Influence of Restricted Localization of Drug on its Action. (Essais d'une nouvelle méthode thérapeutique.) R. de Gaulejac.

42. Drainage of the Popliteal Space.—Hardouin shows in several illustrations the danger of compressing the blood vessels in draining the popliteal space and suggests a technic which renders such injury impossible. In osteomyelitis of the lower end of the femur, for example, he trephines the femur through an incision at the junction of the front and inner aspects of the thigh. The opening through the bone slopes downward slightly, and forceps are passed through it and pushed down and outward until they project under the skin in the popliteal space. The skin is incised a little outside of the median line and a fenestrated drain tube is introduced and then seized by the forceps and drawn back with them through the bone and out through the first opening on the opposite side above. By this means the region is thoroughly drained, while the tube passing through the bone does not come at all in contact with the vessels and causes no disturbance of any kind. This was shown in a recent case in which the parents insisted on taking away the patient, a boy of 5, six days after the drain had been introduced. The child was not seen again for three months, when the drain was found still in place and doing no harm, except for a little redness around the openings, which soon disappeared when the drain was removed.

43. Traumatic Nephritis with Unilateral Edema.—The case described is interesting from the development of the traumatic nephritis a few days after the accident, the enormous edema of the arm and breast on the injured side, the intense pain in the lumbar region, on the same side, and finally, three weeks after the accident, development of serious nephritis in the previously sound kidney proving fatal in ten days. The assumption of development of nephrotoxins best explains certain features of the case.

45. Modification of Injected Toxin Restricted to a Certain Area.—Gaulejac states that his experimental research has confirmed the fact he observed in a case of viper bite; namely, that an otherwise fatal toxin became harmless when it was temporarily localized in a certain limited area. An otherwise fatal dose of cocaine could be injected without harm into the cellular tissue of the hind leg of a guinea-pig after applying a constricting band above to induce venous stasis for two hours at least. After removal of the band the signs of toxic action were few and slight. If all the interstitial fluid in the limb below the constriction were withdrawn it was found to contain nearly all the cocaine injected, and yet injecting this fluid into another guinea-pig failed to cause any appreciable signs of intoxication. He ascribes this phenomenon of reduced

toxicity to three factors: the damming of the circulation, the mechanical influence of the cellular tissue and its power to modify the toxin, and lastly to the antitoxic action of the edema fluids. These three factors vary with the age, the individual and the tissues injected, but they throw light on the mode of action of passive hyperemic treatment, of "fixation abscesses" and on the healing of tuberculous lesions in the lungs during a concomitant bacillary arthritis.

- 46 *Sporotrichosis of the Bones and Joints. (Sporotrichose osseuse et ostéo-articulaire.) De Beurmann, Gougerot and Vaucher.

46. Sporotrichosis of Bones and Joints.—The importance of differentiating bone and joint affections caused by the sporotrichum lies mostly in the prognosis and possibility of effectual treatment. The patient is relieved from suspicion of tuberculosis or syphilis, and can be cured by medical treatment without the necessity for surgical intervention. In a case reported by Josset the affection had dragged along for three years undifferentiated, but was cured in a month by iodo-iodid treatment. The lesion had simulated chronic osteomyelitis and four operations had been performed. The lesions have often been taken for gummy tumors. Cultivation of the sporotrichum from the lesions and experimental reproduction of the osteitis confirms the diagnosis. The cultivation of the germs or the spore-agglutination test is a simple and easy method for differentiating these lesions, and should be instituted in every dubious case of acute, subacute or chronic osteitis. Five typical cases are described in detail and extensive experimental research is reported with illustrations of the manifold lesions that may be induced by the sporotrichum, spontaneously or experimentally.

49. The technic described is similar to that summarized in THE JOURNAL, July 4, 1908, page 73.

50. External Urethrotomy.—Posner relates a case in which it proved impossible to find the posterior stump of the urethra so as to introduce a sound after external urethrotomy, and the urine flowed over the wound. Further efforts at catheterization were abandoned and very soon some of the urine passed through the urethra, the amount gradually increasing until normal functioning was re-established with only a little aid. Expectant treatment is thus justified in the rare cases in which the posterior stump evades discovery. Always, however, under the assumption that there is no retention of urine, but that it is normally voided, although by an abnormal route.

51. Disinfection of Field and Adjoining Skin Before Operations.—König systematically refrains from scrubbing the field of operation and merely paints it and the surrounding skin with tincture of iodine. The alcohol hardens the tissues, holds the bacteria immovable, and has a slight inhibiting action on them while inducing more or less hyperemia in the region, all of which are advantages in surgical work, while the patients

are not annoyed, chilled and depressed as by the usual scrubbing procedures. By thus avoiding danger of chilling, the tendency to postoperative complications on the part of the lungs is reduced. The patient gets his general bath and is shaved long enough beforehand to allow the skin to be thoroughly dry before the iodine is applied. Regions peculiarly sensitive, such as the scrotum and perineum, are not treated with the iodine. The disadvantages of the iodine disinfection are that the field of operation is so discolored that one has to habituate himself to the negro-like aspect to be able to recognize the various tissues. Another disadvantage is that the operation must be done as dry as possible, as fluids wash away the tincture; moist compresses must not be used directly on the painted surface. When the operation is completed he pours a little of the tincture on the line of suture to ensure fine linear scars. He compares this revolutionary passive disinfection of the skin with the experiences with carbolic-acid spray formerly used to disinfect the air in the operating room. It was found that the spray stirred up and mobilized the bacteria, doing more harm than good, and he believes that the scrubbing has the same harmful effect, stirring up the bacteria and washing them into the field and promoting the secretion of the glands, thus bringing germs to the surface which otherwise would slumber peacefully in the depths. To leave them unmolested is the safest course, and he thinks that this is best accomplished by the iodine disinfection of the surface to be operated on.

52. Anuria.—Kümmell reviews his experience with anuria at Hamburg and emphasizes the necessity for regarding anuria as a very serious condition, not to be neglected any more than acute ileus or incarceration of a hernia. The patients sometimes experience apparently no ill results; in one of his cases the patient felt perfectly well, notwithstanding four days of total anuria from obstruction by a kidney stone, and was with difficulty persuaded to allow an operation. In one case the anuria persisted for twenty and in another for thirty days, and normal urination was then spontaneously restored. These are the rare exceptions; the anuria, as a rule, entails a comatous uremic state after a phase of subjective freedom from disturbances. Anuria from renal concretions offers a grateful field for treatment when recognized early. If the x-rays show the stone to be too large to anticipate its expulsion by the natural routes operative intervention should be advised at once without further waste of time. If not larger than a cherry stone, or if its shape permits the hope of spontaneous expulsion, the ureter should be catheterized in the hope of dislodging the stone or stimulating the ureter to more energetic peristalsis, with or without injection of oil or glycerin through the catheter. Casper succeeded in stimulating the ureter by injecting water into the kidney pelvis on the other side, the reflex peristalsis thus induced becoming so vigorous that the uncatheterized ureter expelled the obstructing stone. Kümmell advises the use of the ureter catheter whenever indicated, but if no effect is promptly realized he would not waste further time on it, but proceed at once to the operation. In case there is obstruction in both kidneys his experience confirms the advisability of operating first on the kidney last obstructed. In case the wrong kidney is exposed, by a mistake in diagnosis, he advises opening up at once the other kidney and removal of the concretions. If the stone is in the ureter and the obstruction is comparatively recent it may be unnecessary to open the kidney, but if the obstruction is of long standing the kidney above is necessarily altered; also if the patient is comatous when first seen the kidney should be incised. In his nine cases of concretion anuria in three patients there was only one kidney in each, and these individuals all died, although one might have been saved by prompt removal of the stone. In all his cases the trouble was so advanced that operative intervention had scarcely any chance. The prospects are less favorable with anuria resulting from disturbances in the circulation; internal measures are indicated here, diuretics, saline infusion, venesection and, in extreme cases, decapsulation of the kidney. He has done decapsulation in 30 cases, with recovery in 10 and great improvement in 15 others. It is in-

dicated, he says, in prolonged chronic nephritis before anuria has developed, and also in acute hemorrhagic nephritis with scanty or no urine voided, especially when it is a sequel of scarlet fever, eclampsia or sepsis. Success was pronounced in all his cases of this kind. Catheterization of the ureters is also liable to induce benefit in these cases. It is liable to set up a reflex secretion which may transform the prognosis even in cases of chronic interstitial nephritis with anuria, as also in inhibition of the kidney functioning by toxic and nervous influences. The irritation of the ureter mucosa by the catheter may stimulate the functioning of both ureter and kidney.

53. Roentgen Examination of Surgical Stomach Lesions.—This long communication from Bier's clinic at Berlin is accompanied by 49 illustrations of the Roentgen findings in various cases out of a total of 100 thus examined. Each illustration is accompanied by the clinical history of the patient in question. The findings are recorded on a large uniform diagram of the trunk with blank spaces above for record of anamnesis, palpation, distention, stool, siphonage of the stomach, fasting, and after the test breakfast noting amount, microscopic findings and blood, and, with qualitative reaction, free HCl and lactic acid, and, quantitatively, total acidity and free HCl. A plaster cast is also taken of the stomach in the cases that come to autopsy, which is proving instructive for comparison of the cast of the lumen of the pathologic stomach with the records of the Roentgen findings during life.

56. Strangulation of the Cauda Equina.—Oppenheim and Krause give an illustrated description of two cases in which severe symptoms of an affection of the cauda equina came on suddenly. As there was nothing to suggest syphilis, a tumor was assumed and an operation revealed some compression by a tumor or protuberance in the bone. But this did not explain the sudden onset of symptoms, and they assume that the tumor had caused no appreciable disturbance until the patient stooped to lift a heavy weight. This had squeezed the fibers up above the point of the compression. As the fibers became loosened they spread a little, after which they were unable to slide back into their place below and the whole bundle of fibers was thus incarcerated, as it were. The operation revealed the cauda roots displaced, sagging and spread apart, above the narrow point in the lumen, this incarceration being favored by the dilatation of the veins accompanying the roots. The trouble is aggravated by the resulting serous meningitis.

59. Pathogenesis of Nervous Secretory Disturbances in the Stomach.—Bickel has learned several new facts from research on dogs with a blind pouch made artificially from the fundus of the stomach and separated entirely from the rest of the body except for the arteries and veins. This second stomach has thus no connection with the nervous apparatus except for the minute nerves in the walls of the vessels. This "nerveless stomach" continued to secrete gastric juice of normal composition, and this secretion was stimulated by subcutaneous injection of meat extract or ingestion into the primary stomach of meat, bread or milk, the increased secretion commencing about ten or fifteen minutes after the commencement of the feeding. It is evident that the stomach,

like the heart, can continue its functioning even when deprived of all connection with the nervous system outside of the organ. Also that the stimulus for the secreting function is supplied by the food. His experiences have further shown that the "nerveless stomach" displays no tendency to atrophy or impairment of function; the tendency is rather toward hyperfunctioning. His research was undertaken in connection with an address he is preparing for the approaching International Medical Congress on the "Pathology of Secretion and Motility in the Digestive Canal" with special regard to his theory of the stimulation of the juice-producing cells by chemical substances circulating in the blood. This "blood stimulation" of the cell parenchyma is more or less continuous, and is the principal factor in the gastric secretion. The extragastric nervous secretion mechanism studied by Pawlow has merely a regulating function. Bickel's conception explains the importance of dietetic and purely psychic, suggestive treatment of secretory disturbances. It further emphasizes the psychic element in these disturbances and in the effects of medication and of balneologic and dietetic measures, and the possible curative influence of exclusion or stimulation of certain special nerve tracts.

60. Testing Functioning of Pancreas.—Gross has applied to the stools the casein test which has been found useful for examination of pure pancreatic juice and commercial trypsin. The technic is simple and the reaction occurs at physiologic temperature. It is based on the fact that casein, readily soluble in an alkali, is promptly precipitated by acetic acid, in contrast to the products digested by it. Examination of the stools in 200 cases revealed the presence of trypsin in every instance in which the digestion was normal, while the findings were constantly negative in a case of cancer of the pancreas and in one of complete occlusion of the common bile duct. In another case differentiated as cirrhosis of the pancreas, the test revealed normal pancreatic functioning and the integrity of the pancreas was confirmed by autopsy. In a case of hour-glass stomach the oil test breakfast indicated lack of normal pancreatic functioning, but the casein test of the stool gave normal findings in regard to tryptic digestion. The combination of these two tests may therefore prove useful in diagnosing hour-glass stomach. The intensity of tryptic digestion varied within wide limits on different diets, but showed very little fluctuation on an identical diet. This tryptic digestion is most pronounced on an albumin diet (lean meat), and was not influenced by concomitant gastrointestinal disturbance.

61. Syphilis of the Nervous System.—Engelen describes some atypical cases which throw light on the etiology of certain puzzling disturbances in the cerebrospinal system. In the first the syndrome simulated amyotrophic lateral sclerosis, except that it had been in a stationary stage for twelve years and that there had been pains in the legs at first. There were apparently no syphilitic antecedents but the ophthalmologic findings confirmed his assumption of a possible syphilitic origin previously unsuspected. The patient had wasted a fortune in seeking help from quacks when early appropriate specific treatment would probably have effected a cure years before. In a second case, the symptoms of a spinal cord trouble came twenty-five years after unsuspected syphilitic infection. The clinical picture was dominated by variable root and cord symptoms, pains in the back, neuralgic pains in the legs, and tenderness over the spine, tremor, bladder disturbances and variability of the reflexes. In another similar case the pupil reflex appeared and disappeared suddenly a number of times. These patients were both cured by specific treatment. In another case, the symptoms suggested diffuse basal meningitis plus spinal meningomyelitis, too advanced for relief in a woman of 63.

62. Parasitic Origin of Cancer.—In this communication from von Leyden's cancer service at Berlin, Lewin states that the facts observed in regard to the prevalence of cancers in the animals in certain cages and in human beings in certain houses and families can be explained only by assuming a parasitic origin—that the metabolic products of certain parasites are able to stimulate the cells of the new host to malignant proliferation.

71 *Progressive Paralysis from Standpoint of General Practitioner. R. Thomsen.

64. Multiple Acute Periostitis.—von Jaksch describes a syndrome which has much in common with acute articular rheumatism and probably has sometimes been confounded with the latter. The typical case reported in detail was in a young housemaid and was characterized by multiple periostitis, enlarged spleen and progressive leucocytosis, with such large proportions of eosinophiles that he examined the muscles for trichinosis. Fever kept up for several weeks; the swelling and pain were localized in the shafts of the bones instead of in the joints, and sodium salicylate not only failed to show the slightest benefit but induced symptoms of intoxication even in small doses. The affection finally subsided spontaneously under local application of Goulard's lead water (diluted solution of subacetate of lead with a little alcohol). The metabolic findings did not show any great disturbance in the metabolism. At one time he assumed certain transient murmurs to be due to concomitant endocarditis, but, as the heart findings became constantly normal thereafter, he now accepts them as fever murmurs. He has previously described a case of this same affection with a chronic, progressive and fatal course, and regards it as a morbid entity distinguished by the eosinophilia, myelocytemia and multiple periostitis, the localization of the swellings and pains throughout the entire extremities and the failure of the usual antirheumatic medication.

65. Chronic Intermittent Albuminuria as Relic of Infectious Nephritis.—Eichhorst has observed this intermittent albuminuria in a number of youths and young men and lays stress on psychotherapy to tranquilize the patient and the family, supplemented by careful hygiene and tepid baths, avoiding stimulants and salted and smoked meats, the diet being restricted mainly to milk, vegetables and starchy foods. He never witnessed much benefit from change of climate and none from drugs. Such patients must be careful not to get chilled suddenly, or get wet, and woolen underclothing is advisable. Most of his patients recovered entirely in the course of time, but several years were required in some cases.

66. Demineralization of Tissues Predisposing to Tuberculosis.—Robin's views in regard to the deficiency of mineral constituents of the blood and tissues as the basis on which tuberculosis develops have been described in these columns from time to time. He here cites various objections that have been made to this assumption and answers them in detail. He states that while normal blood contains from 8.39 to 9.109 per thousand parts of inorganic matters, the blood in the "pretuberculous" stage and in the early stages of tuberculosis contains only from 6.38 to 7.85 per thousand. The elimination of inorganic matters is also excessive; analysis of the organs of 5 consumptives and of 2 healthy persons succumbing to accidents showed that the proportion of inorganic matters in the lungs of the latter averaged 12.04 while in the tuberculous lung it averaged only 7.9 parts per thousand. On the other hand, in the sound lung in the tuberculous individuals the proportion was 14.27 per thousand. The contrast was still more marked in analysis of the femurs from both classes. Among the practical conclusions drawn is the necessity for energetically combating gastric hyperchlorhydria which promotes this organic demineralization and thus opens the door to tuberculous infection. A further conclusion is the necessity for supplying mineral elements to aid the organism in its struggle against the infection.

71. **Progressive Paralysis in General Practice.**—Thomsen discusses in detail the differentiation of progressive paralysis, especially from neurasthenia, with which it is most often confounded. Progressive paralysis should be suspected, he says, whenever a man between 35 and 45 complains of nervous or hypochondriac disturbances in the absence of a constitutional predisposition or tangible predisposing factors for neurasthenia, especially when there is a history of syphilis and the disturbances have come on gradually. But he warns that paralysis should never be diagnosed without definite physical findings or a convincing anamnesis. Disturbances in speech are peculiarly suggestive as testifying against neurasthenia.

72. **Action of Fever in Infection.**—Rolly remarks that the generally accepted opinion in regard to febrile temperatures is that they are part of the defenses of the organism but that main injury is connected with them which compels us under some circumstances to strive to reduce the febrile temperature. He then describes experimental research and compares the results with those of others in this line, drawing the conclusion that in infectious diseases there is increased destruction of albumin, both as a result of the high temperature and as a result of the causes inducing the fever. With a temperature under 104 F. the share of the fever in this increased destruction of albumin is comparatively so small as to be negligible. The changes in the corpuscles and in the proportion of hemoglobin are the work of the infectious cause and are not the results of the increased temperature. His experiments showed that the agglutinins were increased in the heated rabbits; the higher temperature favored the production of agglutinins as also of antitoxins and bacteriolytins. On the whole, he concludes, the febrile temperature if not excessive, must be regarded as a process which does much more good than harm. It is a manifestation of the efforts of the organism to neutralize or get rid of the invading bacteria or toxins. Fever under 104 F. should not be combated unless in case of severe disturbances of the central nervous system, such as headaches, stupor or excitement. Antipyretic measures in these cases are not directed against the high temperature so much as against the other symptoms. If antipyretic measures become necessary they should not be too severe, merely tepid baths with mild spongings and possibly a moderate use of antipyretic drugs, never cold baths according to Brand or Liebermeister.

73. **Frequency of Meningitis in Pneumonia.**—Liebermeister states that microscopic examination showed signs of suppurative meningitis in three out of eleven cases of pneumonia in adults. The nervous symptoms were no more pronounced in the meningitis cases than in many without

74. **Drainage of Tuberculous Empyema of the Pleura.**—Schmidt gives an illustrated description of an aspirating apparatus composed of a jar with three tubes in the stopper, one connecting with a catheter introduced into the posterior wall of the thorax, the second tube connected with an air pump and the third with a manometer. When a vacuum is induced in the jar by the air pump, the negative pressure is felt even in the thorax. The connecting tube can be clamped and removed from the connection with the jar so that the negative pressure can be kept up for a long time without discomfort to the patient. This draws out the collapsed lung and proved effectual in the three cases in which the device has been used.

75. **Treatment of Leucorrhea.**—Nassauer deplors the present custom of treating leucorrhea with douches, etc., stating that the same principle should be applied here as to other secreting lesions, that is, to absorb the secretion and keep the surface dry, thus giving the parts a chance to heal. This is accomplished, he says, by dusting with a dry powder, and for this he has found bolus alba the most convenient, inexpensive and effectual. The powder is applied at the same time the walls of the vagina are distended with air, thus smoothing out all the folds and recesses. This he accomplishes with a pear-shaped glass bulb with a reservoir opening into a tube which passes through the glass pear connected with a rubber bulb. The glass bulb closes the entrance to the vagina airtight, and pressure on the rubber bulb fills the vagina with air and at the same time sprays it with the dry powder. He calls this little apparatus a "siccator," and has obtained good results with it in 100 cases. About once a week he orders a cleansing douche followed by the dry powder. His patients included cases of acute gonorrhoeal affections, senile colpitis, inoperable cancer, etc., and all were much gratified by the results.

77. **Substitute for Bismuth in Roentgen Work.**—Taege refers to Lewin's suggestion to use magnetic oxid of iron instead of bismuth, and confirms its value for Roentgen work, but he points out the objections to it in that it is not carried by druggists in stock, as a rule, and usually requires pulverization. These disadvantages can be avoided, he asserts, by substituting ferric oxid, better known as polishing rouge, which is obtainable everywhere as an exceptionally fine and inexpensive powder. He has taken, himself, 750 grains within a short period without disturbance, to test its harmlessness.

78. **Osteomalacia and the Ovaries.**—Cramer attributes osteomalacia to some metabolic anomaly which occurs more frequently in certain localities and in his district affects animals frequently. The aggravation of the symptoms during the menses and pregnancy is certainly due to the increase in size and augmented secretion of the ovaries. He does not regard the ovaries themselves as directly responsible for the osteomalacia. Besides removal of the ovaries, phosphorus and suprarenal preparations and ovarian antibodies are logically indicated in treatment. In a recent case a iii-para of 27, eight months pregnant, presented symptoms of osteomalacia. Castration was advised but refused. After the childbirth the symptoms subsided, but returned again at the next pregnancy in so severe a form that the ovaries had to be removed. To insure completeness the tubes were resected at the same time. The expected abortion did not occur and seven months later a normal child was delivered. The symptoms of osteomalacia subsided immediately after the castration. During the rest of the pregnancy there were no manifestations from the artificial menopause, but a month after delivery hot flashes were noticed. The ovaries from this woman were transplanted in a girl of 22 with pronounced infantilism. Cramer cites this case of osteomalacia as a striking proof of the fact that the osteomalacia is entirely independent of the development of the fetus, but is influenced by the exaggerated functioning of the ovaries.

80. **Arsenic-Tuberculin Treatment.**—Friedmann writes from Brazil to confirm Mendel's statements in regard to the advantage of combining arsenic with tuberculin. The beneficial effect is marked on the appetite.

81. **Urobilin.**—Hildebrandt discusses the occurrence and importance of urobilin in health and disease and especially its relation to jaundice. He describes a technic for determination of the proportion of the urobilin in the urine, declaring that the clinical examination of the patient which omits this finding is incomplete. Fever in itself never induces urobilinuria, and urobilin disappears from the urine in case the common bile duct becomes obstructed. Urobilinuria occurs from abnormal destruction of blood if the liver is sound, but if there is no other abnormal destruction of blood, urobilinuria always indicates some lesion in the liver and local stasis of bile.

93 *Polyserositis. J. Wiczowski.
94 Isolated Defect of Auricular Septum and Its Clinical Manifestations. (Defekt der Vorhofschleimwand und seine klinischen Erscheinungen.) E. Popper.

91. **Bacteriology of Scarlet Fever.**—Schleissner found streptococci almost in pure cultures on the tonsils in every case of scarlet fever examined in its incipency before the sore throat had developed. He was also able to cultivate streptococci from the blood in a large proportion of the 73 cases reported, and the presence of antibodies was also unmistakable, reaching the maximum about the tenth day. It seems evident that streptococci are closely connected with the scarlet fever process, and hence that antistreptococcus treatment can not fail to aid in attenuating the disease.

92. **Femoral Hernia.**—Exalto states that of the 134 patients with femoral hernia operated on at von Eiselsberg's clinic at Vienna during 1901-1908, all but 20 were women. Three of the cases reported illustrate the dangers of forcible reduction at home of an incarcerated hernia; in one case an already perforated loop of intestine was thus pushed back and fatal peritonitis resulted. In 2 cases the femoral hernia developed after a radical operation for an inguinal hernia on the same side. This and other experiences suggest, he says, the advisability of operating on the femoral hernia through the inguinal ring if it is unusually large, even if there is no actual inguinal hernia at the time. By suturing the muscles to the horizontal ramus of the pubis the tendency to femoral hernia is most effectually combated while at the same time the danger of development of an inguinal hernia is averted.

93. **Polyserositis.**—Wiczowski has encountered during the last five years 35 cases of a simultaneous inflammation of several serous membranes, fatal in 4 instances. The polyserositis develops in three stages. In the first there is merely a serous effusion in the pleura, pericardium and peritoneum, but no fever or apparent changes in the internal organs or glands and the patients complain only of general weakness and vague pain in the chest and abdomen. Adhesions form and the condition grows worse under increased temperature, with debility and irregular stools. Exceptionally the condition may improve and the improvement may persist for several years. The third stage is characterized by high fever, cachexia and edema of the feet, and autopsy reveals cheesy degeneration of the lymph glands, parenchymatous degeneration of the internal organs and tubercles disseminated over the serous membranes while the lungs and digestive tract are intact. Treatment can be only by general strengthening measures, forced feeding and possibly injections of some preparation of arsenic, supplemented by early aspiration of the effusion, this latter having a favorable effect on the circulation and nourishment of the regions involved and hastening the development of adhesions which modify favorably the

further course of the affection. The negative findings in the heart, lungs and kidneys differentiate the polyserositis from disease in these organs. He emphasizes the constant absence of the usual symptoms of pleurisy or peritonitis, also the simultaneous involvement of all the serous membranes, suggesting some general cause, which he thinks is unmistakably endotoxins generated in some comparatively small tuberculous focus, these endotoxins reaching and irritating the serous membranes. Some old focus in the lymph glands or urogenital apparatus was discovered in all the cases that came to autopsy. This assumption of the etiology explains the benefit from prompt evacuation of the effusion which removes quantities of these endotoxins while favoring production of adhesions. He is convinced that many cases of alleged "pericardiac pseudocirrhosis of the liver" and "chronic hyperplastic perihepatitis" really belong in this class of polyserositis. A case is reported in a footnote which confirms this view: A woman of 28 with effusions and adhesions in the pleura, pericardium and peritoneum, and with enlarged liver but normal temperature was tapped, and after evacuation of the effusion in the peritoneum a tumor was discovered in the pelvis which proved to be a cold abscess following a spondylitic process. The endotoxins generated in this abscess were evidently responsible for the development of the polyserositis.

- 95 *Radical Operation for Inguinal Hernia by Transverse Incision and Raising the Pelvis. (Radikaloperation der Leistenhernien mittels Haut-Fascienquerschnitts und Beckenhochlagerung.) C. Hofmann.

95. **Transverse Incision for Inguinal Hernia, Raising the Pelvis.**—Hofmann ensures with his incision perpendicular to Poupart's ligament that the musculature, deep fascia and peritoneum are incised lengthwise of their fibers. The herniotomy is much facilitated by his practice of raising the pelvis as soon as the hernial sac is mobilized.

Zentralblatt für Gynäkologie, Leipsic

April 17, XXXIII, No. 16, pp. 553-584

- 96 *Breast Pump. (Eine neue Milchpumpe.) R. T. Jaschke.
97 *Extraperitoneal Cesarean Section. (Extraperitoneale Kaiserschnitte.) H. Freund.

96. **Improved Breast Pump.**—The improvement in the pump, of which an illustrated description is given, consists merely in a "cone valve," a little cone fitting in an opening in the nozzle of the air pump with which suction is applied to the breast. The cone is lifted at will by a spring lever, and thus allows air to enter the glass chamber with which the pump is connected. The breast and nipple recede as air is admitted, but the pump still fits air-tight over the breast. Renewed aspiration with the air pump draws the breast and nipple out again, this intermittent suction and subsidence imitating the natural process of the child's sucking. It is thus possible to empty both breasts completely in from eight to fifteen minutes, so that an infant applied afterward is unable to get any milk. The spring cone valve can be applied to any air pump used for the purpose.

97. **Extraperitoneal Cesarean Section.**—In the two cases reported by Freund he incised the cervix after transverse incision of the abdomen, and was much pleased with the ease and results of this cervical Cesarean section. It is facilitated by the fact that the parietal peritoneum can be readily detached from the abdominal wall, even in the non-pregnant. It is most readily accessible through a transverse incision. The bladder during pregnancy is connected with the uterus only by delicate and loose connective tissue. The peritoneum can thus be easily pushed up and the bladder pushed down or to one side. It is important to turn the uterus from without until the point where the reflection of the peritoneum can be most readily pushed away is brought up for the incision, and the head can be also guided from without to bring it into the incision. He adds that the bladder should not be filled beforehand, and no retractors should be used on the bladder or lips of the wound. The incision in the cervix should be on the median line, and only the suspicious or infected cases require drainage.

98 *Treatment of Gangrenous Appendicitis. A. Montini.

April 15, No. 15, pp. 473-480

99 Bismuth Paste for Roentgen Examination of Fistulas. (Sull'esplorazione dei tramiti fistolosi col processo di Beck.) G. Spelta.

98. Marsupialization of Gangrenous Appendix.—Montini found at the laparotomy in the case described an ulcerating and gangrenous appendix with extensive peritonitis in this part of the abdomen. The cecum was involved in the ulceration to such an extent that he felt compelled to refrain from appendectomy for the time being, and merely drew the appendix outside the abdomen and fastened the wall of the cecum to the lips of the wound all around the implantation of the appendix. By the end of a week the inflammation and tumefaction had subsided to such an extent that the appendix could have been readily resected, but he left it as it seemed to be undergoing a process almost like absorption as the wound healed. The adhesions that formed were sufficient, he thought, to protect the peritoneum against further trouble from the appendix.

Policlinico, Rome*April, XVI, Surgical Section, No. 4, pp. 145-192*

100 *Experimental and Histologic Study of Anastomosis of Nerves. P. Alessandrini.

101 *Sarcoma of the Pancreas. F. Ravenna.

100. Anastomosis of Nerves.—Alessandrini's experiments were made on dogs and showed that the ultimate functional results are better in young than in old animals. In the younger dogs he found that complete restitution of function followed implantation of the hypoglossal nerve in the spinal accessory severed where it emerges from the sternomastoid, or in the other hypoglossal or some nerve connected with the brachial plexus. Even when only a few fibers of the hypoglossal had been implanted in a lengthwise buttonhole in the other nerve the functional results were excellent. For the clinic, in case of danger of aspiration pneumonia from paralysis interfering with swallowing, he advises implantation of the hypoglossal in its sound mate, which was easily done in his experiments. An interval of two or three months between the severing of the nerve and its anastomosis did not interfere with the restoration of function, but it was found necessary to resect the enlarged end of the stump.

101. Sarcoma of the Pancreas.—Ravenna gives an illustrated description of two cases of sarcoma of the pancreas, in one of which a suprarenal capsule was imbedded in the depths of the pancreas, the suprarenal capsule on the left side being missing otherwise. This patient was a boy of 15, the other was a man of 50.

102 *Diagnosis of Hypernephroma. (Mezzi diagnostici del cosiddetto ipernephroma del rene.) D. Taddai.

103 *Experiment in the Passage of Micro-organisms through Wall of Bladder. (Sull'attraversamento dei microorganismi attraverso la parete vescicale.) D. Taddai.

102. Diagnosis of Hypernephroma of the Kidney.—As a contribution to the diagnostic measures for the so-called hypernephroma of the kidney, Taddai relates a case in which an intermittent tendency to hematuria was noticed for a few weeks, in a boy of 11, with moderate fever and finally dysuria and retention. A tumor palpated in the kidney was removed and the various tests for hypernephroma were applied but with negative findings except the Croftan iodid-starch test, the Fedoroff test with mydriasis in the frog eye, and the nitrate of silver test. He attributes the positive findings even in these tests to a simple osmotic process or to the non-specificity of the tests—the iodid-starch test having given equally positive findings in his hands with an adenocarcinoma of the breast.

103. Passage of Micro-Organisms Through the Bladder Wall.—Milone's extensive experimental research has confirmed the assumption that when the bladder walls are sound and the flow of urine normal, micro-organisms are unable to find lodgment and injure the walls and pass through them—all of which is favored, on the other hand, by stagnation of urine.

PROBLEMS AND PROCEDURES IN CRANIAL SURGERY*

CHARLES H. FRAZIER, M.D.

Professor of Clinical Surgery, University of Pennsylvania
PHILADELPHIA

The problems of cranial surgery are manifold and the procedures correspondingly diverse. In this age of specialism it falls to the lot of some, whether because of greater opportunities unsought or natural inclination, to acquire greater familiarity with this or that particular field of endeavor. The surgery of the central nervous system, as that of other systems, requires not only a practical knowledge of the technic, but an intimate knowledge of the physiology and pathology of the structures to be dealt with. The successful and intelligent abdominal surgeon not only must have acquired dexterity in the performance of certain operative procedures, but he has familiarized himself with the physiology, normal and perverted, and with the pathologic aspects of the organs under consideration. It is not enough for him to be able to perform a gastroenterostomy, but he must be able to recognize, if not before at least at the time of operation, the conditions which indicate the propriety of such an operation. It is not to be assumed that one who would engage in neurologic surgery must have either the knowledge or the skill of the neurologist in the diagnosis of affections of the nervous system, but he must have a good working knowledge of the functions of the organs he is dealing with and of the naked-eye appearance of the pathologic lesions to which they are subject. Too much stress has been laid in the surgery of all organs and systems on operative technic, important and essential as it is, and not enough on a fundamental knowledge of the physiology and pathology. It is not enough for a surgeon to be able with skill and dexterity to expose the affected region, but when it is exposed he must be able to recognize the precise nature of the lesion with which he is confronted and to decide promptly and intelligently to what extent he is called on to interfere. It is not my purpose to treat the various subjects to be alluded to, either comprehensively or in detail, but to review in very general terms some recent developments in the field of cranial surgery.

TRIGEMINAL NEURALGIA

While one could hardly say that the last chapter of the surgery of trigeminal neuralgia has been written, it may at least be said, without fear of contradiction,

that of all the operations on the central nervous system in none has a greater degree of perfection been attained and with none are the results so eminently and enduringly satisfactory. The attempt in recent years to substitute for operations on the ganglion or the sensory root various peripheral procedures is not justified by the results. The peripheral avulsion of Thiersch is the most satisfactory of the minor extracranial procedures, but, no matter how radical the removal of the nerve may seem to be, recurrence or subsequent involvement of other branches is the rule rather than the exception. The more recently advocated therapy of alcohol injections has not as yet given more than transitory relief, as the pain returns on an average within seven months.

The element of danger, so conspicuously dwelt on in many treatises on this subject, no longer justifies the apprehension which still lingers in the minds of the profession. The mortality, often quoted at 22 per cent., may be said now to be a gross exaggeration. In Horsley's series of 120 cases the mortality was 3.3 per cent. This report was made in 1905, and I have no doubt but that even a better showing will be seen in his more recent experiences. In my own series of twenty-seven cases I have lost but one patient—the sixth of the series. There have been no fatalities since 1905 (mortality 3.7 per cent.).

It is not necessary to dwell at length on the technic of the operation on the ganglion or its sensory root; suffice it here to emphasize certain features that seem of greater moment. Speaking only of personal preferences, the operation should be performed with the patient in the sitting posture as a matter of convenience to the operator, as a means of controlling hemorrhage, and as affording the most direct view of the deep-seated structures. The upper branch of the facial nerve must be avoided. The approach to the ganglion is made through an auriculo-temporal opening. This opening, somewhat posterior to the one usually prescribed, is preferred to others because it affords the most direct and shortest route to the sensory root of the ganglion. There is no advantage and some disadvantage in working through too small an opening. An opening 3 to 4 cm. in diameter is none too large and enables the brain to be elevated with less danger of trauma to the temporal lobe. The bone should be rongeured away as far down as the infratemporal ridge, and the middle meningeal artery ligated and divided in every instance, as the point of its convergence from the foramen spinosum is directly between the eye of the operator and the structure he is endeavoring to expose.

Though there is some difference of opinion as to some of the preliminary steps, the final one has provoked the most discussion. It is interesting to see how, chronologically considered, this step has been simplified. At

* An address before the Toronto Academy of Medicine, March 4, 1909.

first it was thought best to remove the ganglion *in toto* and the unsuccessful attempts in the early days were responsible for the so-called recurrences; later on some surgeons regarded removal of only the outer and posterior aspects of the ganglion as sufficient; and, still later, the division of the second and third divisions as

Fig. 1.—Table with special head extension and posture of patient preferred in operations on the Gasserian ganglion and in all craniotomies for pretentorial lesions.

they leave the ganglion, with the interposition of foreign material to prevent regeneration of new tissue. Finally, Spiller proposed the "sensory root" operation, providing it could be proved, as was done at that time by animal experimentation, and subsequently by clinical observations, that, once divided, the root was incapable of regenerating itself. The first operation, performed with the deliberate intention of dealing only with the sensory root, I undertook at Spiller's suggestion in 1901, and from that time to this have modified it only in exceptional instances. It has been truly and aptly called "the physiologic extirpation" of the ganglion and will become, I believe, if it has not already come to be, the operation of choice. Whether the root is divided or avulsed, judging from my results, is a matter of no consequence. Once having grasped the nerve it is quite as easy to avulse as to divide it and the results are equally effectual. I have done both a number of times and have never been able to discover any difference either in the immediate or ultimate effects. Division or avulsion of the sensory root gives just as positive assurance against the recurrence of neuralgic attacks as does the removal of the appendix against the recurrence of appendicitis.

CEREBRAL TRAUMA

Our attention in recent years has been directed to certain phases of cerebral trauma not to be found in earlier classical writings. In the latter we find discussions *in extenso* on the difference between concussion and contusion, elaborate presentations of the mechanics of fractures of the skull and of the effects of injuries by *contrecoup*. The indications for surgical therapy were confined to hemorrhage and depressed fracture and the treatment of contusion and concussion consisted chiefly in the administration of opiates, calomel and the iodids. The work of Cannon on the pathogenesis of cerebral edema and the experimental investigations

from Kocher's laboratory on the relation of increased intracranial tension to the circulation has opened up a new field to the practicing surgeon. Leaving out of consideration cases of either local or general compression of the cranial contents, the direct result of hemorrhage or depressed fracture—a group in which the indications for operative intervention are self-evident—there is left a large class, the essential feature of which is the damage to the brain itself. I am referring especially to cases of cerebral edema of traumatic origin, cases in which the function of the vital centers may be destroyed or altogether arrested, either directly by the injuring force or indirectly by circulatory disturbances. Cerebral edema causes increased intracranial tension; this in turn first interferes with the venous circulation, causing passive hyperemia, then with the arterial circulation, causing anemia. These problems in pathologic physiology have all been worked out in the laboratory and we can follow them in certain instances by analogy on the human subjects.

Cases of cerebral contusion with cerebral edema, with or without fracture, may be called border-line cases, because neither active surgical intervention nor invariable palliation can claim them all. Under what circumstances, therefore, is operation to be resorted to—this is a problem of great proportions. I can only allude to a few pertinent facts, and first to the relation of blood pressure to intracranial tension.

Fig. 2.—The first case in which the sensory root was deliberately divided as a substitute for the extraction of the ganglion; from photograph of patient taken when operation was performed in 1901.

As a result of the obstruction offered the circulation by the increased intracranial tension a comparative rise in the blood pressure has been observed in the laboratory, and this phenomenon has been suggested as an index of the gravity of the condition. But I wish to say quite emphatically that repeated observations on the human subject in cases of intracranial trauma have had, al-

most invariably, negative results; while exceptionally the blood pressure may be more or less elevated, in the great majority it is not, even though the symptoms indicate a very serious intracranial injury and the operation reveals tremendous intracranial tension. The elevation of blood pressure so frequently observed in the experimental laboratory when the cranial contents are me-

Fig. 3.—Patient shown in Figure 2, from photograph taken in 1908. The region outlined in front of ear only hyperesthetic; the remainder is absolutely anesthetic. There has been no recurrence of the neuralgia.

chanically encroached on is not present under corresponding physical conditions in the living subject. Therefore, as a guide to the grade of intracranial tension or an indication for operative intervention, blood pressure observations with the instruments now available are practically worthless.

Second, as to the relation of papilledema to increased intracranial tension, it has been asserted that papilledema is a more or less constant accompaniment of those cases of intracranial trauma in which there is obstruction to the venous circulations, the stage of *Stauungs-hyperämie*, which, according to Kocher's scheme, is the first stage of cerebral compression. For the past two years at the University Hospital Dr. G. E. de Schweinitz, the ophthalmic surgeon, has made repeated observations for me on all varieties of serious head injuries and I am privileged by de Schweinitz to say that in only two cases has he been able to detect a papilledema, one of three and one of seven diopters. In other words, papilledema as a manifestation of intracranial tension the result of trauma is the exception, not the rule, and therefore can not be considered of any great moment as a means of diagnosis or as a guide to treatment. The pathogenesis of papilledema is most perplexing. That it is not due solely to such encroachment on the cranial contents as may be brought about experimentally has been borne out by many investigations.

The third point to which I wish to refer has to do with the decompressive operation and its application in

cases of serious contusion of the brain, with or without a basal fracture. The decompressive operation recently has been much talked about and frequently practiced for the relief of certain symptoms of brain tumors, internal hydrocephalus and the like. That it has a field in cerebral trauma I am also quite convinced, but in what cases it is indicated there may be some difference of opinion. Thus, for example, the statement has been made¹ that it should be performed invariably in cases of basal fracture because nearly all the symptoms are due to intracranial pressure. According to Cushing, the mortality of basal fractures is 87 per cent. In times past a great many patients died as a result of secondary infection of the meninges, but in our modern management, infection as a factor has been generally eliminated, so that the fatalities now are due to injury to the brain structure, whether it be a contusion, laceration or edema. In the past ten years the mortality in all cases of basal fracture, not including those with fracture of the vault, at the Episcopal Hospital was 59 per cent. That this mortality could be reduced by operating in selected cases would seem more than likely. But, inasmuch as so large a percentage recover spontaneously, routine surgical intervention is obviously unnecessary and therefore unjustifiable. How are we to determine in which cases to interfere? If we attempt to analyze our cases they would seem to fall naturally into three groups.

Group 1.—Those in which damage to the brain has been so great that, decompression or no decompression, the patients die. The fatal tendencies in these cases are easily recognized, and as a rule the patients survive the injury but a few hours. The autopsy reveals laceration and hemorrhage in and about the brain substance. Thus, for example, a patient (No. 2138) aged 60, falls on the pavement and strikes the back of his head; he is

Fig. 4.—Patient one week after division of the sensory root; showing the position of flap within the hair line and use of an automobile goggle for protection of the eye

brought to the hospital unconscious, with a slow pulse and deep but stertorous respiration; there is inequality of the pupils and left facial paralysis; complete muscular relaxation. Bloody fluid is removed by lumbar puncture and the blood pressure registers 180 mm. Hg; in a few hours the temperature begins to rise rapidly and the pulse to become accelerated: immediate decompres-

1. Cushing: Johns Hop Bull., February, 1908

sion is done; the brain is found edematous, the pial veins distended, and here and there are small blood clots over the surface; there is little pulsation, either before or after the dura is opened. The course of events is absolutely uninfluenced by the operation, the condition becomes progressively worse, and the patient dies a few hours later.

Group 2.—Those in which the symptoms at no time appear serious enough to threaten life. There may be, as in a case I have in mind, complete unconsciousness or deep somnolence, slow pulse and respiration, perhaps a papilledema and evidence of injury to some of the cranial nerves, as the oculomotor, abducens or facialis. The symptoms persist for several days and then show signs of abatement and the patient recovers. To illustrate this group I may cite a case with all the symptoms of basal fracture. Though unconscious for several days, the patient's condition was at no time serious; about the tenth day, when he had recovered sufficiently to make examination possible, a paralysis of one arm

Fig. 5.—From a photograph taken in the course of a craniotomy on a patient referred to in Group 2. Note pial clot in motor area.

was discovered. On exposure of the motor area a thin layer of clotted blood, in the arm center was revealed, evidently the result of a torn pial vein. The latter was ligated, the clot removed and the paralysis disappeared. Not only would decompression in this case have been unnecessary, but had it been resorted to the clot would not have been revealed and the patient would have been subjected to the risks of two instead of one operation.

Group 3.—Those in which the patient's condition, though not desperate from the first, becomes progressively more serious; the unconsciousness deepens, relaxation takes the place of restlessness, the respirations become more stertorous and Cheyne-Stokes in type and the pulse slower; in a later stage there may be signs of beginning breakdown of the respiratory and circulatory functions; it is in this group that decompression should be considered as a means of saving life. Whether we should decompress in the temporal or in the subtentorial region I am not prepared at the present time to say. Theoretically we would select the subtentorial re-

gion, where the greatest relief of pressure would be afforded the most important structures; namely, the vital centers in the medulla. We have been at work for some time on this problem in our experimental laboratory and hope in the near future to be able to draw some interesting and valuable conclusions. It is needless to say that, when undertaken, the operation should be performed without any anesthetic and should be conducted as rapidly as possible.

ANESTHESIA AND HEMORRHAGE

In operations on the central nervous system and, more particularly, in subtentorial lesions, with the cardiac and respiratory centers often just on the verge of a breakdown, so that even comparatively slight insults are not tolerated, a greater responsibility rests on the anesthetizer than in any other class of cases, except perhaps in those of grave toxemias, as of peritonitis. So important is this feature of cranial operations that under no circumstances should an operation be undertaken unless the services of a skilled anesthetizer are available. This problem has been met in my service at the University Hospital by the appointment of a permanent salaried official, a graduate nurse, who gives her entire time to the work and has proved eminently satisfactory.

In addition to the anesthetizer, the operating staff includes an assistant, whose duty it is solely to observe and record the blood pressure at frequent intervals throughout the operation. With these precautions one may proceed with the operation with the fullest assurance that the condition of the patient is being carefully watched and that one's attention will be drawn at once to the first suggestion of any alarming symptoms.

As a matter of convenience to the operator, as well as of safety to the patient, some means should be adopted to control hemorrhage from the scalp in the performance of craniectomies or craniotomies. This is a much simpler problem when operating for pretentorial than for

Fig. 6.—Cryer's spiral osteotome, used by the author in all his craniotomies.

subtentorial lesions. A great variety of devices have been suggested, such as those of Kredel, of Haidenham and others. Dawbarn's sequestration anemia sounds plausible and I have no doubt it would be a delightful sensation to perform a bloodless operation under the regulated pressure of a Sauerbruch's chamber could the element of expense be eliminated. I have come to the conclusion that the simplest and in other respects the most satisfactory is a simple, old-fashioned Petit's tourniquet. The rubber tubing which I had been in the habit of using was either too light or too loose and by pressure on the supraorbital nerves occasionally caused severe frontal neuralgia. By means of the key on the Petit's tourniquet the amount of pressure can be regulated to a nicety and the breadth of the tape lessens the likelihood of harmful pressure on the nerves. The tourniquet is rendered thoroughly sterile by boiling or in the autoclave and may be handled whenever necessary throughout the operation; in applying it a small compress of gauze should be inserted beneath the tape over each temporal fossa. At the conclusion of the operation the pressure should be released sufficiently to en-

able one to see the principal bleeding points, opposite which the scalp sutures should be introduced to control bleeding.

TECHNIC

The technic of the osteoplastic flap has been well-nigh perfected. Many instruments have been devised for this purpose, but each surgeon must select for himself the one with which he can develop the greatest dexterity, the one with which he can section the bone with a minimum of trauma and the least expenditure of time. My experience has been solely with the spiral osteotome (Cryer's), an instrument which has seemed to me to meet every indication and enables one to reflect a flap of considerable dimensions in four or five minutes. The initial and the only opening in the skull is made with a conical fraise, so constructed that it can not penetrate the dura and usually jams before it penetrates even the internal table. Once the brain is exposed, some attempt should be made to prevent its surface becoming chilled by the use either of hot compresses or hot irrigations. Before replacing the flap bleeding from

other reasons to reopen the flap, as I have had occasion to do twice, the second operation may be performed without either local or general anesthesia. None of the manipulations cause discomfort except those which involve the dura. Grasping the dura with forceps, the introduction of dural sutures, hot applications or douches excite some pain, but the pain is quite bearable and calls forth but little protest on the part of the patients. If the two-stage operation is resorted to, therefore, one should bear in mind the feasibility of conducting the second stage without subjecting the patient to the inconvenience or the risk of a second etherization. The manipulations of the brain substance itself are painless.

Fig 7—Exploratory craniotomy. Note the position of the patient, size of the flap and the absence of bleeding in operative field even without the use of hemostats

Fig 8—Section of brain, illustrating characteristics of an inoperable tumor. Note the distance of the tumor from the cortex and its infiltrating non-encapsulated character.

every source should be under control, iodoform wax being used for the bone and the finest catgut ligatures for the pial vessels—the two common sources of hemorrhage.

Cortical stimulation may be used to advantage when it is desirable to determine with accuracy the situation of one or the other of the motor centers. As a matter of observation, it is interesting often to determine the precise relation of the lesion to the center involved, as, for example, in cortical epilepsy or in cases of tumor attended by convulsive seizures. It should be borne in mind, however, that with two or three successive stimuli the centers may be so exhausted as not to respond to subsequent attempts, no matter how strong the current.

The two-stage operation formerly so widely advocated is no longer necessary; so little blood is lost and time consumed in exposing the tumor that, when found, there is no reason why the surgeon should not proceed with its removal. We are speaking now of tumors of the cerebrum, not of the cerebellum, where there are greater technical difficulties and less favorable operative subjects to deal with. If it should be necessary for

OPERABILITY OF BRAIN TUMORS

If the estimate is to be based on post-mortem statistics from 4 (Knapp) to 7 (Walton) per cent. are operable (Tillman places the percentage at 6.5). This, however, is a very inaccurate way of estimating the operability of tumors since at the autopsy table the size and relations of the tumor may differ very radically from that at the time when an operation should have been undertaken. As Horsley aptly says: "Post-mortem records can never teach what the careful study of the living tumor exposed in an operation can demonstrate, since in almost every case the former condition is what we may term inoperable." But unfortunately surgical therapy in cases of brain tumor is too often regarded as the *dernier ressort* and the operation has been postponed so long that, even when exposed at the operating table, an overwhelming majority are beyond the stage at which removal is possible. If my own experience is any criterion, I have seen but seven, or possibly eight, cases all told in which the tumor was operable. These do not include cysts, tuberculoma or gummata. The operable tumor must be accessible;

that is, either on or just beneath the cortex and sufficiently well defined to enable one to determine its limitations. The inoperable, on the other hand, is a deep-seated or infiltrating growth. No attempt should be made to remove a growth of an excessively vascular infiltrating type. The attending hemorrhage may prove fatal, and, if the patient survive and the growth be imperfectly removed, recurrence will be rapid and the expectation of life no longer than after a decompression, if as long.

Fig. 9.—Type of operable tumor; from photograph of fibro-sarcoma removed from the cerebello-pontile space.

THE SURGERY OF THE POSTERIOR FOSSA

The exploration of structures subtentorial constitutes a problem very different from that involved in pre-tentorial lesions. From a large and varied experience I have formulated for my own service certain definite conclusions. They are as follows:

1. Generally speaking, exploratory operations and decompressive operations in the posterior cranial fossa are fraught with more risks to the patient than are those in any other part of the brain: a certain percentage of patients will die while under observation, or just as the anesthetic is begun, or when convalescence seems well established, apparently irrespective of operation. Those deaths are usually sudden, not forewarned, and are due to central disturbance of the respiratory apparatus. By artificial respiration I have seen the life of the patient sustained for eighteen hours, but the respiratory center never resumed its function.

2. If, added to exploration, an attempt is made to remove the tumor the risks of the operation are increased to such a degree that I consider such attempts, where the tumors are malignant and adherent to adjacent structures, as absolutely unjustifiable. This statement refers particularly to the tumors of the cerebello-pontile angle and to the malignant type, especially the endotheliomata. There may be instances, as in the encapsulated types of fibrosarcoma, or, of course, in the benign fibroma of the auditory nerve, when removal is quite feasible and may be curative in its effect.

3. The great majority of tumors are situated in the pontile angle—at least, if my experience does not differ very radically from that of other operators. To express this relative frequency more definitely, I should say that in my whole series of exploratory operations for subtentorial lesions there was but a single case in which the tumor was discovered in the substance of either cerebellar hemisphere.

4. While assuming a skeptical attitude regarding the operability, so to speak, of tumors in this region, I am most optimistic as to the results of decompression. In the subtentorial, more than in the pretentorial, lesion is decompression clearly indicated once the diagnosis is made. Papilledema is so much more constant and optic atrophy so inevitable a sequel that, apart from other considerations, operation should have been resorted to, as a rule, months before the patient is brought to the surgeon.

5. Lumbar puncture, either as a diagnostic or therapeutic measure, should never be resorted to. The number of fatalities from this apparently harmless procedure are so great as to make it absolutely prohibitive. I am speaking now chiefly from the observations of others as recorded in literature, as I have in but one instance ventured to practice it, and then only after a decompressive operation had been performed. In this case the effects, while not alarming, were most distressing. For forty-eight hours the patient had a violent headache and a peculiar vasomotor disturbance, which manifested itself in a deep red flush of the cutaneous surface of the neck down to the level of the clavicles, quite symmetrical and sharply defined. This manifestation of vasomotor disturbance was quite unique in my experience, although the circulatory irregularities which one sees not infrequently in cerebellar lesions are, in all probability, due as much to disturbance of the vasomotor as of the cardiac center.

Not wishing to describe in detail the steps of the operation, I may add a word or two as to the incision and size of the opening. For most cases it is not necessary to make a bilateral opening; that is, to remove the skull from over both cerebellar hemispheres. It is taken for granted that the osteoplastic flap is not appropriate for operations in this region, and, as the

Fig. 10.—Incision for a unilateral suboccipital craniectomy. Stab wound in center of flap for drainage.

bone is not to be replaced, it has seemed to me unwise to leave permanently unprotected both hemispheres. An adequate opening is one which enables the operator to explore thoroughly the fossa on the suspected side without inflicting undue trauma on the cerebellum, pons, or medulla. Comparing the results of those cases in which I have made a bilateral with those in which a unilateral opening was made, I have come to the conclusion that in the majority of cases a perfectly satisfactory

exposure is obtained from a unilateral opening. On repeated occasions my records show that the deeper structures of the cerebello-pontile angle, as the auditory and facial nerves, were easily demonstrated to onlookers in the course of an operation. The nearer the external margin of the opening approaches the mastoid process the less displacement of the lobe will be necessary to explore the pontile angle. The opening should be large enough to prevent the cerebellar hemisphere, which when under great tension protrudes far beyond the level of the skull, from impinging against the edge of the bone. The cerebellum is much more easily lacerated than the cerebral tissue and must be handled with great delicacy. It is always possible to enlarge the opening so as to include the bone on the opposite side when the occasion demands it, but the larger the opening the more time is consumed and the more blood lost. If viewed from the standpoint of decompression a unilateral suboccipital opening will for obvious reasons afford proportionately greater relief of tension to the structures in the subtentorial region than a unilateral temporal opening to those in the pretentorial region.

Displacement of the hemisphere in one direction or another to explore the respective surfaces of the cerebellar hemisphere must be done with great gentleness and in this maneuver direct pressure on the medulla must be avoided. Many fatalities attending exploration or attempts to remove tumors are undoubtedly due to the effect of trauma on this structure. One might infer from certain illustrations that the cerebellar hemisphere can be dislocated to an almost unlimited degree, but this is far from the truth. In fact, one should always be content with a minimum rather than a maximum exposure.

Particularly after operations upon the posterior fossa has it been noticed that cerebrospinal fluid escapes through the drainage tract in much larger quantities than after the usual pretentorial exposure. This excess is no doubt due to the proximity of the large basal cisternæ and to the influence of gravity. When the drainage material is removed at the end of twenty-four hours there may be a continuous discharge of cerebrospinal fluid for several days. When the drainage tract closes the fluid may accumulate under considerable tension. This may give rise to some transitory disturbances, such as nausea and vomiting or other signs of pressure, or if the wound has not been carefully and properly closed the cerebrospinal fluid forces its way through between the margins of the wound and establishes a fistula which is sometimes difficult to close. The continuous flow of cerebrospinal fluid may be itself a serious matter, as, apart from the danger of infection, gradual exhaustion and death may ensue. Therefore, I wish to emphasize the importance of so making the incision in the various layers, the cutaneous and the fascial, that one overlaps the other. If this precaution is taken there can be no direct communication between the surface and the cerebrospinal space, and the chances of fistula formation are reduced to a minimum.

To obtain a better exposure of the cerebello-pontile space I once suggested the propriety of removing a portion of one cerebellar hemisphere. At the time the proposal was made, now some years ago, I had practiced it but once, and since then only twice. In discussing this proposal in his address before the British Medical Association three years ago Sir Victor Horsley, and since then Borchardt, Sachs and others, rather assumed

that the partial extirpation of a lateral lobe was a part of my routine technic. It is because this suggestion has been given so much notoriety that I mention it here again in order to correct a misapprehension. My position in this matter would be correctly stated by saying that there are exceptional instances in which a portion of one lateral lobe might with propriety be removed; instances in which an adequate exposure could not be obtained by a liberal opening or by emptying the basal cisternæ or by evacuating a lateral ventricle. From the practical point of view I have never seen any untoward effects from this procedure, and theoretically, judging from the experimental observations of Luciani, we have reason to believe that one portion of a hemisphere has the power of compensating for that which, either by atrophy or removal, has been thrown out of commission. I recently examined a patient from whom six years ago I removed from one-third to one-half of one cerebellar hemisphere and found no evidence of any dis-

Fig. 11.—Author's special operating table and position preferred for operations on the posterior cranial fossa. Position of patient on the side is maintained by special appliance attached to deltoid region.

turbance which could be attributed to loss of cerebellar tissue.

The performance of an operation for the exposure of lesions in the posterior fossa requires as much experience and practice as that for the removal of the Gasserian ganglion. There are several features in the technic which seem to me worthy of mention. First, as to the position of the patient, having tried various ways, I have selected the head-up-lateral posture as the most desirable. In this position venous hemorrhage is minimized, respiration is not interfered with—a very important consideration in this class of cases—by slight flexion of the head the field of operation is quite accessible, the anesthetic can be administered more easily than in the prone posture and in exploring the pontile space. As the most direct approach is from the region of the mastoid along the posterior aspect of the pe-

trous bone, I find that with the patient on his side I can see, without stooping and without the aid of artificial light, into the depths of the posterior fossa. On a table designed for these operations the position of the patient is easily maintained and the degree of elevation is readily adjusted to meet the needs of the individual case.

It should be borne in mind that not infrequently in exploring the cerebello-pontile space the necessary manipulations, or possibly a residual blood clot, may cause some transitory disturbance of the function of the cranial nerves to be found in this region. This is especially true of the facial, auditory and glossopharyngeal, and occasionally of the trigeminal. Difficulty in swallowing has been observed a number of times. The surgery of the acoustic nerve is still in its infancy. The principal indications are persistent tinnitus of labyrinthine origin and aural vertigo. To one familiar with the technic of the surgery of the posterior fossa the operation is not difficult; at least, the nerve is readily exposed, although its isolation from the seventh, which it almost sur-

inasmuch as it has assumed so conspicuous a place in cranial surgery, I feel obliged to present some of its salient features.

The operation has a wide application and should not be reserved for tumors only; epilepsy, chronic meningitis, with or without hydrocephalus, and trauma should be included among the indications. But with tumors we should not be content with purposeful palliation unless the tumors can not be localized or can not be removed. The ease with which the simple decompressive operation can be performed, its growing popularity and the immediate relief it affords are tempting surgeons to be content with palliation, and if the habit becomes too prevalent some operable tumors will be overlooked.

Fig. 12.—Simple temporal decompression. Note the fibers of the split temporal muscle; the reflected flap of temporal fascia; the crural incision in the dura; dural flaps reflected and the distention of the pial veins.

rounds, is not so easily accomplished. There are but five or six cases on record. During the past year Balance divided the nerve for painful tinnitus, and at the request of Dr. Mills I performed a similar operation for persistent vertigo. Up to the present time the results as a whole have not been satisfactory.

DECOMPRESSION

From what has been said of the operability or inoperability of pretentorial tumors it will be seen at a glance that in the great majority of instances palliation is the most that the surgeon can offer, but palliation in cases of brain tumors means a great deal more than is usually implied when the term is referred to other incurable conditions. It means restoration or preservation of vision, relief from headache and from vomiting, the three symptoms which together render the patient's life miserable and unendurable.

Decompressive operations have been written and talked about so much of late that to treat the subject exhaustively would but involve much repetition. But,

Fig. 13.—Patient shown in Figure 14, ten days after operation Heinal protrusion twice the size, under tremendous tension and without pulsation.

In looking over my records I find that in the majority of cases decompression was preceded by exploration and without increasing the mortality. It is a very simple matter to decompress over the temporal region through the opening that was made for exploration, as the base of the osteoplastic flap is almost always in this neighborhood. I should like, therefore, to enter a plea against the growing tendency to resort to decompression without first carefully searching for the tumor.

To this general rule there may be an exception, however, as when the conditions call for immediate relief and the opportunity for careful study and localization of the growth has not been afforded. Three such instances occurred in my own practice.

It is needless to emphasize the importance of early operation in cases in which localization is difficult or sometimes impossible. The habit of indefinitely prolonged courses of iodid of mercury with the hope that some definitely localizing or diagnostic symptom may be developed should be deprecated. During this unparadonable delay the optic nerve may become so atrophied

that restoration of vision is out of the question. If in the course of six weeks or two months the condition is practically unchanged and the suspicion of tumor is reasonably established, decompression should be resorted to without delay, in the hope that subsequently, with the appearance of localizing symptoms, the tumor may be found and removed.

The propriety of resorting to decompression in advanced cases when the patient is already in deep stupor may be questioned. Bruns (quoted by Spiller), for example, advises against it. I recently operated in a case of this description for Spiller. The patient was so stuporous that no anesthetic was required; the operation did not influence in the least the subsequent course of events. A striking exception to this rule was brought to my attention in a patient referred to me by Dr. Mills. She was brought to the hospital unconscious; following decompression she not only recovered consciousness, but was relieved of all the symptoms of intracranial tension, was able to leave the hospital and has resumed her household duties.

As a rule the effects of decompression are so beneficial that one should not question the propriety of the operation whenever there is a reasonable hope of the patient's surviving the ordeal. There are, however, exceptions to the rule. In some instances the operation seems to have little or no effect, and in others, though quite exceptionally, the relief of intracranial tension may be followed by some aggravation of these symptoms. Thus, about ten days after a bilateral decompression, a patient who had been under the care of Dr. Van Pelt, suddenly became somnolent, aphasic and paralyzed on the left side of the face and left arm. A hasty examination of the field of operation found a decided change in the condition as noted the day before. From a hernia under little tension, and with visible pulsation, the hernial protrusion had become more than double the size, was under tremendous tension and pulsation was absent (see Fig. 14). Thinking the sudden change in the condition might have been due to rupture of the middle meningeal artery, I laid bare the field of operation, but there was no evidence of subdural hemorrhage; the brain appeared congested, of pinkish color, and a section removed for microscopic examination was reported as showing evidence of hemorrhagic encephalitis. In this case I attributed this sequence of events to a hemorrhage into the cerebral tissue. The sudden relief of intracranial pressure withdrew the support to which the vessels were accustomed, and, not being able to withstand the intravascular pressure, the vessels ruptured and hemorrhage ensued. What in most cases has been attributed to a more rapid growth of the tumor after exploration may be nothing more than a diffuse extravasation of blood or the edema which follows the sudden relief of intracranial tension.

The term decompression implies not simple trephining, but the removal of a considerable portion of bone on one or both sides of the cranium, together with the removal of the dura or a crural incision in it. In subtentorial cases decompression is advisable in the occipital region, and in the pretentorial cases, as Sanger suggested, in the silent area of the right temporal region, and as Cushing proposes, by splitting temporal muscle.

The expectancy of life after the operation is of no little interest; even though the patient survives the operation but a year it is no little thing to be able to preserve sight, allay vomiting and relieve headache for

the days that remain. But a greater prolongation of life may be anticipated; from my own clinical experience there are patients alive from three to six years after the date of decompression.

Reference has already been made to the problem of decompression as applied to cerebral contusion; whether decompression combined with drainage may be beneficial in inflammatory conditions, as in suppurative meningitis, is problematical; that it may be of service in unilateral internal hydrocephalus there is no question. According to Kocher epilepsy may be favorably influenced by the *Ventilbildung*, the establishment of an opening large enough to prevent the increase in tension, which he believes precedes the attacks. While there may be theoretical and practical objections to this hypothesis, I am quite convinced that in some cases at least the improvement after the operation is very striking. Though acknowledging some skepticism as to the theory on which the operation is based, I have resorted to the operation a number of times and have under observation

Fig 14—Patient after bilateral temporal decompression in a case of brain tumor which could not be localized. Note the establishment of a hernia cerebri only on one side.

some fifteen to twenty patients already operated on. For obvious reasons the results should not be published until five years have elapsed. Whatever may be said, *pro* or *con*, as to the propriety of operating in cases of the so-called idiopathic type, in cases without a suggestion of a focal lesion, I have been surprised to find in a large percentage of cases the brain when uncovered presented some gross pathologic lesion (adhesions, edema, the remnants of an old pachymeningitis, etc.) so frequently that it would appear as though the so-called idiopathic type was a little less prevalent than we were led to believe before we had so many opportunities as now to study the living pathology of the brain and its membranes.

This subject is a massive one and I am quite conscious of the necessarily superficial way in which it has been treated. There are many problems in cranial surgery but imperfectly grasped and many more still untouched. Though accompanied with many disappointments, the study of these problems is a fascinating one and offers a fruitful field of investigation.

THE CINCINNATI MILK SHOW

W. A. EVANS, M.D.
Commissioner of Health
CHICAGO

The medical world is more and more making a study of the public health. Following closely on the progress made in the field of preventive medicine, we are seeing the principles therein established applied to large communities. The work of a health officer no longer means merely the collection of vital statistics, the suppression of communicable diseases and the abatement of nuisances, but involves the larger one of sanitary instruction of the public. There are in this country practically no colleges which prepare men for this expert work, and with the large percentage of our health boards

ably no city had greater need for such a campaign, and in no city could the work have been made more difficult, for past boards of health and milk inspectors have stood squarely in the way of any progress along the line of better milk.

The practice of feeding wet distillery waste to milk cows (abolished fifty years ago in New York), with the dairy conditions that are always to be found with such feeding, had made it impossible commercially to maintain dairies on a proper milk-producing basis in this vicinity. Dr. S. E. Allen, of Cincinnati, began a vigorous agitation for better dairy conditions in 1906. The community did not understand as well as it should the importance of better milk, and Dr. Allen was not backed up by his health board as he should have been. The present health officer, Dr. Mark A. Brown, has also failed to receive the kind of support that he should have had.

Largely through the influence of Dr. Allen, who had previously gone out of office, the State Legislature of Ohio in January, 1906, passed a bill prohibiting slop-feeding to dairy cows; and the organized medical profession, and especially the milk commission and its secretary, Dr. Otto P. Geier, conducted a three months' campaign in behalf of this bill with eventual success, although it was opposed by most powerful interests. The bill having passed, the difficulties were not at an end, and the milk commission and the medical profession were very active in securing administration under this bill.

The milk commission began to make arrests of the violators of the law, and so intelligently, fearlessly and consistently did they proceed in awakening public sentiment that they found all of the civic organizations back of them when they recently presented to the city council for passage

an ordinance abolishing the present board of health and creating a non-partisan board, to be composed of experts properly qualified to carry on some continuous plan of guarding the city's health. This measure was passed in face of the fact that the council was strongly partisan.

From the very beginning this commission has gone direct to the people, and the politicians have heard in no uncertain terms from the sentiment thus crystallized in the public mind.

And so it was with the milk show. The moment the plan of the same was placed before the various civic organizations the milk commission was given their hearty support. And with what results? Twenty thousand people visited the pure milk exhibit in five days; hundreds of dairymen attended the four sessions of the dairy institute, where addresses were made by some seventeen authorities on the following general headings:

Fig 1—Cincinnati Milk Show Exhibit of the Dairy Division, U S Department of Agriculture; good and bad dairy conditions

whose personnel reflects some political affiliations in control of the work of the health officer, it is not to be wondered at that some of our cities are not making the desired progress in their health affairs.

The city's health, as well as its disease, is more and more becoming the business of every conscientious physician. The medical man is contributing his valued share to the universal improvement of health in cities. The Cincinnati Milk Show, which I visited the first week in May, was most distinctly a physicians' movement, and a report of the same should be of interest to the profession at large.

The Milk Commission of the Academy of Medicine of Cincinnati, now entering on its third year of activity, has just brought to a successful conclusion the Cincinnati Milk Show, the most comprehensive educational attempt of its kind ever made by any American city in the crusade for the betterment of its milk supply. Prob-

What Constitutes Good Milk and How It Is to Be Produced.
The Necessity of Cooperation Between the Consumer and Producer.

Detection and Cure of Diseases in Dairy Cattle.

Effect of Cattle Diseases on Milk.

The Breeding, Selection and Feeding of Dairy Cows.

A national certified milk contest added to the interest of the exhibit, while fifty shippers of milk into Cincinnati competed for the prizes offered in the market milk contest. A complete dairy equipment exposition was another feature added to educate the dairymen in the methods of modern dairying. A public meeting brought the milk show to a close.

And now a bit more into detail. What factors entered into the great success of this milk show? To begin with, a broad conception of the subject and a gathering together of all of those elements which would make for success. The underlying principle was the education of the consumer, as well as the producer, and that a better understanding between the two would make for an earlier solution of the problem of a clean milk supply. "Sanitary instruction is better than sanitary legislation."

The cooperation of the U. S. Department of Agriculture, Bureau of Animal Industry; the Ohio State University; the Ohio Dairymen's Association, and other local dairymen's associations, as well as the Business Men's Club; Antituberculosis League; Women's Club; Chamber of Commerce, and federated organizations were secured. Splendid quarters were obtained right in the heart of the city for the exhibits which I shall now briefly discuss.

THE PURE MILK EXHIBIT

This part of the milk show was held in a spacious vacant banking room, and was given over largely to the exhibit supplied by the Dairy Division of the U. S. Department of Agriculture and that of the Pathological Division of the same department. There was displayed a series of enlarged photographs so arranged that the good and bad dairy conditions were brought out in startling comparison. Charts of all kinds indicated the bacteriologic findings in milk produced under good and bad conditions. The tuberculous cow was shown next to a healthy one; badly ventilated barns next to modern ones; sanitary methods of milking alongside of slovenly methods. Thus in one glance the public could appreciate the basis for the agitation which has been carried on for an improvement of the milk industry.

The next and perhaps most popular exhibit was that held under the Pathological Division, Bureau of Animal Industry. In a large glass refrigerator were shown fresh specimens from the abattoir showing tuberculous lesions in dairy cattle. On top of the refrigerator were

placed the alcoholic specimens of the same human lesions under glass. On the wall near by were hung fine colored drawings of bovine and human tuberculous lesions in the various organs. A series of colored plates showed the transmission types of the tubercle bacilli. While the presence of tuberculosis in dairy cattle and its attendant danger is accepted without discussion by the profession, an ocular demonstration like the above was valuable in convincing the lay mind of this menace to public health. The elimination of this source of tuberculosis is difficult on account of public apathy, and compulsory pasteurization of the bulk of any city's milk supply will be necessary until the people acquire a better understanding of this danger, and then compulsory testing of all dairy cattle with tuberculin will be enforced.

The federal authorities were represented by a number of experts who throughout the day explained the

Fig 2—Cincinnati Milk Show. Tuberculosis exhibit, Pathological Division, U. S. Department of Agriculture.

various phases of the exhibit, and one can not speak too highly of the educational value of their work done in Cincinnati.

COMPLETELY EQUIPPED MILK LABORATORY

Here the government sought to enlighten the public and the dairymen in the details of milk examination. A complete laboratory for bacteriologic and chemical work had been provided by the local committee. Consumers and producers were invited to send in their samples of milk for a report thereon. The simpler methods of judging milk were also explained, and it was rather remarkable to see how the people crowded about this demonstrator continuously. A series of Petri dishes affixed to plate glass showed the rather interesting variation in bacterial growth in certified milk, fair market milk and filthy market milk. Black paper had been pasted on the opposite side of the glass so that the

colonies could be readily seen. This display gave to the uninitiated a fair understanding of the methods employed in judging the milk for its cleanliness.

MINIATURE MODEL DAIRIES

A valuable object-lesson to the farmer in this milk show was a miniature reproduction of the dairy buildings of one of the certified farms located at Louisville, Ky., which was loaned by the Neill Roach Dairy Company.

Every detail of construction, location of buildings, interior of barn, milk house, quarantine stables, detention barns, was shown, even to the point of the system of ventilation.

A topographic reproduction of the farm, roads, buildings, etc., of the Walker-Gordon farm at Plainsboro, N. J., added much value to this phase of the object-lesson in modern dairying.

Fig. 3.—Cincinnati Milk Show. Exhibit showing dairy conditions in Maryland and in foreign countries.

EXHIBIT OF MARYLAND STATE BOARD OF HEALTH

This collection of pictures was most interesting, showing not only the dairy conditions in the State of Maryland, but a most remarkable collection of photographs indicating good and bad dairy conditions in foreign climes.

SHOWING BY MEDICAL MILK COMMISSION

The Cincinnati Academy of Medicine, about three years ago, appointed a milk commission for the purpose of encouraging the production of a clean milk which might safely be prescribed by the medical fraternity of that city. That they accomplished that purpose was evidenced by the splendid showing made by the producers of four inspected and two certified milks put on display. The combined output of these six dairies which are supervised by the experts of the milk commission now totals 600 gallons a day. These producers forgot

for the time their rival interests and worked together in an admirable spirit of cooperation. Their products, properly capped and sealed with the insignia of the milk commission, showed the public in the purity of what milks they might have absolute confidence.

Panoramic views of the farms under certification and interiors of the dairy buildings were displayed and made a marked contrast to the slovenly city dairy portrayed by the government as an example of what constitutes insanitary dairying.

Among the many interesting charts of the milk commission exhibit was one which caught my particular fancy and which showed some of the earlier work of the commission. An inquiry was made into the kinds of milk purchased by the various hospitals in Cincinnati and was amplified by a search as to how the milk was cared for in the hospital and in what condition it finally reached the patient. The results shown by the

charts were most startling. The majority of the hospitals had purchased milk the chemical composition of which was very fair, but on account of indiscriminate skimming of the same along its route to the patient it reached the patient almost invariably with a very low fat content. Milk that averaged 4 per cent. in the store-room was given to the patient with a butter fat reduced to 3.2 per cent. and 1.8 per cent. From the standpoint of cleanliness, even grosser carelessness in the handling and keeping of the hospital milks was shown. While the content of the store-room milk was found to be anywhere from 17,000 up to 700,000 bacteria to the cubic centimeter, it was in all instances very much worse when received by the patient. Open vessels, lack of ice, etc., accounted for the tremendous increase. In one instance where a hospital was buying

inspected milk which showed a bacterial count of 17,000 in the store-room, the patients on the second floor were receiving that milk in which the bacteria now numbered 5,000,000.

The direct result of this investigation was an improvement in the care and handling of milk in all of the hospitals, and two hospitals now buy only inspected milk.

Many other charts, among them one showing the keeping qualities of certified milk in storage for the four weeks preceding the milk show, added interest to this phase of the exhibit.

This medical milk commission has taken on itself a much broader scope of work than the average commission. It has conducted a three years' campaign of education, the culmination of which was this milk show. In this it points the way for all other milk commissions. Every county medical society would do well to appoint

a similar committee, whose business it would be, not only to provide for them a clean milk, but to become conversant with the milk problem of that particular community and assist in its solution. If the health officials are doing their duty, such committees would only cooperate, but should they fail in giving proper service to the people such committees would properly bring the matter to the attention of the public.

TO MEET IN ATLANTIC CITY JUNE 7

The Cincinnati commission is credited with organizing the American Association of Medical Milk Commissions. In less than two years this association, through its central office, has been the means of so stimulating the interest of the profession in their work that the number of commissions has increased from twenty-two in 1907 to forty-eight at this time. This association meets each year one day previous and at the same place where the meetings of the American Medical Association are held. This year the conference will be held at the St. Charles Hotel, Atlantic City, N. J., June 7, 1909, at 10 a. m. Medical men interested in this work are invited to attend the meeting.

THE NATIONAL CERTIFIED MILK CONTEST

The secretary of the Cincinnati Commission is also secretary of the National Association of Medical Milk Commissions. Great pains were, therefore, taken in securing the cooperation of the various milk commissions of the country to the end that their producers should enter this contest. When the entries closed and the government took charge of the milk, which was in cold storage, they found twenty-five samples from certified milk producers scattered all over the country from San Francisco and Seattle on the west to many cities scattered along the Atlantic coast to Toronto on the north, not forgetting cities in the middle west and northwest. Almost without exception these milks arrived in splendid condition and the government officials say that there never was a contest in which the bacteriologic findings were so uniformly low. That clean milk, well iced, can be kept almost indefinitely was shown by the distribution of the prizes. Mr. Lovett, of Brighton, N. Y., took first; Mr. F. E. Moore, Alford, Pa., second; while honorable mention went to producers in California, New Jersey, Toronto, Canada, and Ohio.

An annual national certified milk contest was encouraged by the Cincinnati milk show in that the first prize, a silver cup, was offered by the American Association of Medical Milk Commissions, and the second prize, also a silver cup, was offered by the Certified Milk Producers' Association of America. They are presented with the understanding that they are to be held

by the fortunate winner until the next annual contest, when they will be passed on to the producer of certified milk receiving the highest score in that contest. A different system of collecting the samples for the certified milk contests will be placed before the members of these two associations at their meetings in June. This method, if adopted, will remove the only possible unfairness that might exist in similar contests in the future. It would seem that these two associations in offering these two cups in this way have made even more certain the continued progress of the certified milk commission idea, and that these annual contests will more and more unify the standards of the various commissions and thus widen their usefulness. There is no longer any doubt but that the professional control of dairies in the production of certified milk is a success and that the field of educational work of such medical milk commissions is practically unlimited.

Fig. 4.—Cincinnati Milk Show. Miniature models of dairy farms and prizes in national certified milk contest.

DAIRY EQUIPMENT EXPOSITION

The exchange floor of the Chamber of Commerce which is above the rooms given up to the pure milk exhibit was devoted to the dairy implements exposition. Thirteen implement manufacturers and supply houses here exhibited modern dairy equipment apparatus. The exhibit included a great variety of utensils, from a milk-pail to a gasoline engine, and attracted not only dairymen, but others as well. It was useful in that it placed before the dairymen those things which help to make their business more profitable and their product more acceptable. The handling of milk is becoming more and more a mechanical operation. Better appliances looking toward the safeguarding of a pure product are constantly appearing on the market. Boards of health are continually raising the standards and enforcing stricter requirements in regard to the milk supply, and these

throughout the four sessions. The local committee enjoyed the cooperation of the dairy department of the Ohio State University and the Ohio Dairymen's Association, who assisted not only in securing the speakers, but in bearing the burden of that expense. The papers brought out most interesting discussions, in which the dairymen took active part. A better mutual understanding of the conditions between the producer, dealer and consumer was the natural result. To those consumers who heard these discussions and to the far larger number who read about them in the newspaper reports of the meeting was brought home the conviction that his inquiry should be, not "How cheap," but "How good is the milk which I buy?"

103 State Street.

ACUTE PANCREATITIS *

WILLIAM FITCH CHENEY, M.D.

Professor of Principles and Practice of Medicine, Cooper Medical College, and Physician to Lane Hospital
SAN FRANCISCO

REPORT OF CASE

History.—A man aged 29, always previously well, was taken suddenly and violently ill on the evening of July 19, 1908. After working all day and eating his supper as usual he had a feeling of weight in his stomach, drank some water for relief, and was immediately afterward seized with very severe pains. These persisted until an hour later he vomited a large amount of material, watery in character, which he described as "black-looking stuff." This vomiting recurred later in the night and altogether he brought up a large amount of this dark-looking fluid. After a hypodermic injection of morphin the pain and the vomiting gradually ceased and he slept. The next day he had hiccoughs and these persisted more or less constantly thereafter until July 25. During this period, July 20 to July 25, he had only a little pain, but vomited from time to time, at least once a day, irrespective of food taken, and could not take food because it caused nausea and distress. The hiccoughing was relieved only by stomach washing, but would recur after a short interval of relief. The material removed by lavage was only a greenish, watery fluid. At first, following the onset of his illness, he was bloated and tympanitic, but this gradually subsided. He had no fever of consequence and his temperature was mostly subnormal. After July 25 there was no more hiccoughing, but the patient continued to vomit at least once every day and was, therefore, fed exclusively by rectum; nevertheless he kept on vomiting at times, a very sour material, often dark brown in color. He had no pain, but rapidly grew very weak. Finally on July 30 he was brought to Lane Hospital, in San Francisco, when the foregoing history was elicited.

Examination.—On July 31 the following notes were made of the patient's condition: "His face looks drawn, haggard and cyanotic. The upper half of the abdomen is more full than the lower, especially in the right hypochondrium. The abdominal wall is rigid in the epigastrium and the right and left hypochondrium, so that deep palpation can not be made; furthermore, the patient complains of great tenderness when deep palpation is attempted. The liver dullness measures 10 cm., the splenic 7 cm. The temperature at this examination is normal, the pulse 100, full and regular." Further investigation showed that the urine was normal. The white blood corpuscles numbered as high as 35,000, and 84 per cent. of these were polymorphonuclears. The temperature by rectum was normal in the morning, but rose to 101 each evening.

Course of Disease.—The vomiting persisted several times each day, of dark brown material, showing blood both by gross inspection and by chemical tests; at times the vomitus was greenish and apparently free from blood, but at other times

it appeared to be almost pure blood, with clots, dark and coagulated. The pulse rapidly grew weaker and more rapid as the vomiting continued and no food could be taken. Operation was advised; was accepted, and was performed by Dr. Emmet Rixford on August 5. A large abscess was found in the gastrophatic omentum and about 8 ounces of pus evacuated. The patient died at 4 a. m. on August 7.

Autopsy.—The partial autopsy permitted showed the pancreas sloughed and partially destroyed, with perforation into the lesser peritoneal cavity; but no perforated gastric ulcer as had been suspected as a cause of the abscess. The stomach, duodenum, pancreas and gall bladder were removed and submitted to Dr. William Ophüls for pathologic examination. His report on them was as follows: "A large portion of the pancreas, between the middle and the distal thirds, is necrotic and infiltrated with pus; there are no fat necroses and nothing abnormal about the pancreatic duct; one of the smaller branches opens abruptly into a defect caused by the necrosis. The bile ducts and gall bladder are normal, the latter filled with normal bile. Smears from the bile show nothing abnormal, no bacteria; smears from the necrotic mass show a few polynuclear leucocytes, many small encapsulated Gram-positive diplococci, a few short Gram-negative rods. Cultures from the bile show a mixture of Gram-positive diplococci and Gram-negative bacilli; cultures from the pancreas show a few Gram-positive diplococci and many Gram-negative bacilli. Diagnosis: Abscess of pancreas (pneumococcus infection), with perforation into lesser peritoneal cavity; infected bile."

Several important questions are suggested by this case.

I. HOW FREQUENTLY DOES ACUTE PANCREATITIS OCCUR?

To this one can only answer that it certainly is not a rare disease. It seems, however, to have gone undiscovered for many years, like appendicitis and cholecystitis; and, as with these latter, the cases have multiplied rapidly since the condition began to be studied.

It is generally admitted that the first satisfactory description of the symptoms of acute pancreatitis was given by Fitz, in 1889, in his Middleton-Goldsmith lecture,¹ though cases had been recognized before that time and reported by several clinicians and pathologists, especially in Germany. Since that date, and during the past decade particularly, the disease has received an increasing amount of attention; cases have been frequently reported in medical literature, and the pancreas has become an object of especial interest.

In April, 1907, Egdahl² was able to collect from literature 105 cases reported up to that date by various observers. No doubt as time goes on and the manifestations of the disease become better understood it will be found that acute pancreatitis occurs even more frequently than is now realized.

II. WHAT CAUSES THE DISEASE?

The answer to this question can be summed up in one word—infection; but there are several possibilities open as to the route of infection. This may occur (a) from the intestine through the ampulla of Vater and the pancreatic duct, or (b) from the gall bladder, by obstruction of the ampulla and the passage of infected bile from the common duct up the duct of Wirsung, or (c) by direct extension of a duodenitis through the wall of the duodenum into the head of the pancreas, or (d) by infected emboli carried by the blood stream from distant parts. The consideration of these various possibilities suggests the clinical conditions that may precede and underlie acute pancreatitis. Most cases have

1. *Roston Med. and Surg. Jour.*, February and March, 1889, cxx., Nos. 8, 9 and 10.

2. *Johns Hopkins Med. Bull.*, April, 1907.

* Read before the San Francisco County Medical Society, April 13, 1909.

been found to be associated with disease in the gall bladder; in Egdahl's list, 44 cases of the 105 belonged to this group. There may be a gallstone blocking the ampulla of Vater, or there may be, as in the case herewith reported, simply infected bile without evidence of gallstone formation.

The next largest group of cases, 32 in Egdahl's list, is associated with gastroduodenitis, especially that due to alcohol. This causes the pancreatitis indirectly, by occluding the ampulla by inflammatory swelling and so permitting retrojection of bile into the pancreas; or directly by infection along the common duct and the duct of Wirsung from the duodenal surface, or else through the duodenal wall.

The cases reported as occurring secondary to other local or general infection, such as appendicitis, mumps, typhoid fever and boils, are best explained as due to transmission of infection by the blood. That infection of the pancreas does not occur more frequently is probably owing to the bactericidal power of pancreatic juice; and when acute pancreatitis does occur there must be some other factor that diminishes this bactericidal power. Whether this is always stasis due to obstruction at the ampulla, or whether it may be some change in the chemical composition of the secretion, is so far only matter for conjecture.

III. HOW CAN WE RECOGNIZE THE DISEASE CLINICALLY?

From all the reports of published cases, as well as from the one above described, it is evident that the onset is violent and sudden.

The first symptom is usually pain, situated in the epigastrium, of great severity, usually paroxysmal in character; vomiting occurs soon after pain begins, is persistent and severe, and frequently the vomitus is bloody; collapse quickly follows, with rapid and weak pulse, prostration and possibly death within twenty-four or forty-eight hours. If the patient survives the shock of the initial symptoms, hiccough is likely to become a persistent feature; the bowels are obstinately constipated and the symptoms of localized peritonitis in the upper abdomen develop, with a low grade of fever and irregular chills, in addition to the previous vomiting, hiccough and prostration.

The physical signs at the outset are simply those of intense tenderness in the upper abdomen, with marked rigidity of the abdominal wall; later on there is commonly an increased fulness or even a visible and palpable swelling extending across the epigastrium and into each hypochondrium. The laboratory evidence is not diagnostic nor does it serve to differentiate acute pancreatitis from several other conditions simulating it. In the blood, there is quickly a high leucocyte count, with an increase in the polymorphonuclears. As regards the urine: first, it does not show sugar except in rare instances, because the pancreas is not uniformly or entirely destroyed; second, the absence of indican is a point of importance in differential but not in direct diagnosis; but third, Cammidge asserts that the urine gives the characteristic pancreatic reaction in all cases of acute pancreatitis in which he has examined for it—nine in all. Other observers, however, have not been so fortunate. The feces show an excess of undigested fat; but the constipation that usually accompanies the disease rarely permits of the use of this method of diagnosis.

Taking all these facts into consideration we must conclude that there is no absolutely certain way to

recognize acute pancreatitis clinically. In a discussion on the diagnosis of this disease, before the Section on Medicine of the British Medical Association, at its meeting in August, 1907, Cammidge remarked:³ "In reading through the recorded cases of acute pancreatitis I was much struck by the small proportion in which a correct diagnosis was made at the bedside prior to operation or postmortem examination. Taking 50 recently reported cases, the authors of which were presumably acquainted with the symptomatology of the condition, I find that 12 were diagnosed as perforating gastric ulcer, 12 as intestinal obstruction, 4 as peritonitis, 2 as appendicitis, 2 as cholecystitis, 1 as strangulated hernia; in 12 no diagnosis was made; and only 5 were correctly diagnosed as acute pancreatitis."

IV. WHAT SHALL WE DO FOR ACUTE PANCREATITIS?

It may be objected that where no positive diagnosis can be made, no plan of treatment is rationally indicated. But that is not altogether true. The symptoms are such that we can promptly arrive at a conclusion, limiting the diagnosis to one of a very few conditions arising in the upper abdomen, namely; acute pancreatitis; perforation of a gastric or duodenal ulcer; perforation of gall bladder; acute intestinal obstruction; or embolism of the superior mesenteric artery. As a matter of fact, each one of these demands surgical interference if life is to be saved, and the indication is clear for laparotomy just as soon after onset as the patient's condition will permit it. This is the only question to be answered—whether to operate early or to wait; whether the patient will be harmed more by the shock of the operation than by the delay. There is no medical treatment for acute pancreatitis, except for the early symptoms, such as morphin for pain and stimulants to tide over the crisis of imminent collapse.

In the discussion already mentioned, before the British Medical Association, Osler said:³ "Taking a large series of cases, 90 per cent. of those not operated on died, and of those operated on more than 50 per cent. recovered." In the recent work by Mayo Robson and Cammidge on the pancreas, the following statement is made regarding acute pancreatitis:⁴

Of fifty-nine reported cases of operation during the acute stage twenty-three recovered. Although this is a large mortality, it must be borne in mind that the disease usually ends in death if not treated surgically. The lessons which one may learn from recorded cases are not to wait until the system is overweighted with absorbed poison before operating and not to spend too long a time over the operation.

Shreve Building.

Science and Morality.—The value of science as a support of morality is emphasized by Prof. A. P. Mathews in the *Popular Science Monthly*, March, 1909. "Science," he says, "besides its material conquests of Nature, has developed human pity and compassion. . . . Science has shown the human race to be actually one great family, of which the misery of any part necessarily affects the happiness of the whole." It has also taught the value of truth and candor. Duty or responsibility to others should be the key-word of education. The ideals of science should become the ideals of every one. Efficient moral education must inculcate habits of logical thought. Moral conduct is conduct which increases human happiness. Human affection is the real basis of morals. It has been greatly stimulated by science, and anything which hinders or opposes the development of human affection in each individual and each nation is seen to be necessarily immoral.

POSTOPERATIVE ILEUS*

WILLIAM H. WATHEN, A.M., M.D., LL.D.

Surgeon St. Anthony's Hospital, University Hospital and
City Hospital, and Professor of Abdominal
Surgery and Gynecology, Medical Department of the University of Louisville
LOUISVILLE, KY.

For postoperative ileus we should substitute postoperative paralytic obstruction, partial or complete, temporary or permanent; for the word "ileus," in its etymology, has no pathologic significance and should be eliminated from surgical nomenclature.

Partial or complete intestinal obstruction may be either primarily paralytic, or mechanical, followed by loss of motility and peristalsis if operation is delayed.

The primary paralytic form of obstruction may be caused (1) by violent inhibitory impulses transmitted to the muscle walls of the intestines from the central nervous system by the splanchnic nerves through the sympathetics; (2) by impairment or destruction of the energy in the neurenteric plexus, and the myogenic force in the walls of the intestines on which motility and peristalsis depend, resulting from the poisonous action of bacterial enzymes from the intestines or the peritoneal cavity on the nerves or muscles in the bowel wall; or from traumatism; or (3) by the combined action of the central inhibitory splanchnic impulses, with impairment or destruction of the energy in the neurenteric plexus, and myogenic force in the walls of the intestines, caused by bacterial poisons or traumatism.

Mechanical intestinal obstruction may be caused by adhesions, constricting bands, volvulus, intussusception, hernia, etc., and if not relieved promptly by operation the bowel above the obstruction becomes dilated and then paralytic, and the ileus can not usually be differentiated from the primary paralytic form.

In order better to understand paralytic bowel obstruction, and also mechanical bowel obstruction, simple, or followed by paralysis, it is necessary to study the research work done on the gastrointestinal tract bearing on its anatomy, physiology, motility and bacteriology. While these observations have been made on animals, usually in good health, it has been shown that in treating such obstructions in man we may, with few exceptions, be governed by the results obtained. It may be urged that these experiments were on healthy animals, while in paralytic or mechanical obstruction we are treating patients with a pathologic condition of the gastrointestinal tract, and, while this is true, it is also equally true that we can not correctly understand the pathology until we learn the normal anatomy and physiology. In studying the anatomy and physiology of the gastrointestinal tract, while we recognize form, we must not forget that to understand better the physiology and motility, and often the pathology, we must make the division by function and not by form from the inlet to the outlet. This is in keeping with the embryology of the digestive tract, which arises from the foregut, the midgut and the hindgut. From the foregut is developed all the tract to a point in the duodenum below the entrance of the bile and pancreatic openings; in this part of the tract digestion is nearly completed, but there is but little absorption. From the midgut is developed the lower part of the duodenum, the

jejunum, the ileum and cecum, ascending colon and the transverse colon to the splenic flexure; in this part of the intestine nearly all absorption of digested products results. From the hindgut is developed the splenic flexure, the descending colon, the sigmoid flexure and the rectum, the part of the intestine used for storage and the expulsion of feces and gas.

The motility of the gastrointestinal tract is involuntary, except at the inlet and the outlet, and this is essential, because there must be a voluntary control of what enters the stomach and of what passes out of the rectum. The upper third of the esophagus is entirely controlled by the central nervous system, this control disappearing in the middle third, and is entirely abolished in the last third. The sigmoid flexure is nearly entirely controlled by the central nervous system, and the rectum is entirely so. In all other parts of the tract, the motility is involuntary, and a nervous system, known as Auerbach's plexus, lies in the muscle walls and imparts energy to the circular and longitudinal muscles, giving them force to propel the food and liquids through the tract after fixed laws.

The innervation to the stomach and intestines from the central nervous system is from the vagi, the fibers of which enter and become interlaced in the medulla oblongata, and the splanchnics, right and left major and minor, from the thoracic ganglia, which transmit impulses through the sympathetics. The impulses through the vagi to both stomach and intestines are mainly motor, but under certain conditions inhibitory impulses may be transmitted, but probably these are merely temporary, the inhibition being quickly followed by increased motility. The impulses transmitted through the splanchnics both to the stomach and intestines are inhibitory, and this inhibition may be so increased by injury to the testicles, kidneys, posterior structures of the peritoneal cavity, or in a state of profound asthenia, etc., as, temporarily at least, to control the neurenteric energy and myogenic force in the intestinal walls. When all inhibitory impulses from the central nervous system have been abolished by the division of these nerves, gastric and intestinal peristalsis continues practically normal, and the food products may enter the colon as soon as before such division, and sometimes sooner. It will also be noted that in cases in which the splanchnics are cut the relative characteristic rapid carbohydrate discharge and the slow proteid discharge is not materially changed. This may continue for weeks with but little change in the nutrition of the animal.

If the motor impulses of the vagi be destroyed by vagus section, leaving the splanchnics intact so as to allow the continuous inhibitory impulses, the discharge of both carbohydrate and proteid food is distinctly retarded, but the same relative rapidity of discharge is maintained. This slowness of discharge is, however, partially recovered from after several days.

When all extrinsic impulses are removed by both vagus and splanchnic section, the gastric and intestinal motility is nearly normal, indicating that the relatively slow discharge of food from the stomach and intestines after vagus section is caused not alone by the absence of vagus motor impulses, but also by the depressing or inhibitory influence of the splanchnics.

The characteristic rapid discharge of carbohydrate food, and the slow discharge of proteid food through the pylorus into the duodenum, after destroying central motor or inhibitory impulses, shows that the discharge from the stomach is mainly under local control, the

* Read in a Symposium on Sequelæ of Abdominal Sections, before the American Gynecological Society.

peristaltic wave in the body of the stomach and the antrum being induced by the mechanical irritation of the food, while the opening and closure of the pyloric constriction is under local reflex control, induced by the presence of acid chyme. While in much of the gastric secretion, and probably in all the secretion of the digestive enzymes in the intestines, the glands are activated by a hormone or secretin, we have not been able to show that chemical mechanisms have caused motility in any part of the gastrointestinal tract, this being entirely local reflex in the nerve plexus in the intestinal walls, caused by distention. Why these nervous mechanisms controlling motility should be so adaptable, allowing the food to remain in the stomach, the duodenum, the small intestine and colon, each a sufficient time to complete normal digestion and absorption, we have not been able to learn. We have learned, however, that this orderly march may be easily disturbed by central nervous influences, caused by excitement or shock, or by injury to certain organs, or retroperitoneal structures in the abdominal cavity, or by traumatism to abdominal viscera, especially the stomach and intestines.

That we may better appreciate the meaning and the significance of paralytic obstruction, we should first correctly understand the motility in the intestines as seen in normal peristalsis after food is taken into the stomach, which passes on, observing fixed laws—the laws of the intestines. The food remains in the stomach or any part of the intestines until it is acted on properly. The proximal bowel then develops onward peristaltic waves of contraction, and simultaneously the immediate distal bowel relaxes so as to allow the food to move toward the least resistance. The onward contraction peristaltic waves and the distal relaxation continue in a regular order until the food is passed into the cecum and colon, but these coordinating movements are easily disturbed by irritation or injury to the intestines, and in some cases of intestinal wounds by projectiles the bowel becomes temporarily paralyzed, thereby greatly lessening the amount of fecal matter that would otherwise empty into the peritoneal cavity and increase the dangers of infection. This conservatism is so protective as to allow a patient to recover from a timely operation who would otherwise die. But if the bowel is simply irritated at any point, it immediately contracts in the part oral to this point, and relaxes in the part aboral, which relaxation may extend a considerable distance. In all forms of so-called ileus, temporary or permanent, there must be a partial or complete destruction of peristalsis, which may be restored promptly, slowly, or continue until death. If the obstruction is complete, the peristalsis aboral to the obstructed part may be but little if at all disturbed, and we often see the distal bowel collapsed and apparently in a state of health, when the proximal bowel is greatly distended with feces and gas, its walls filled with infarcts, or in a state of death. We see the same condition in mesenteric thrombosis, in which there is neither mechanical obstruction, peritonitis or inflammation of the bowel walls. "Dynamic" signifies "pertaining to motion as the result of force"; hence the word should be excluded in any form of intestinal obstruction, unless there be cases caused by a temporary or continued spasmodic contraction in the ileocolic sphincter, or in some part of the bowel. Starling may be correct in his observation that, while splanchnic stimulation may cause complete relaxation of both the circular and longitudinal muscles of the small intestine, thereby

destroying peristalsis, it produces a strong contraction of the muscle fibers of the ileocolic sphincter. While vagus stimulation may cause an initial inhibition of gastrointestinal peristalsis, quickly followed by an increased motor force, it does not cause contraction at the ileocolic junction. Antiperistalsis is normal in the cecum and the ascending colon, and, while it is contended that there is no antiperistalsis in the small bowel, we have positive proof that in both mechanical and paralytic obstruction the intestinal contents, if not spontaneously expelled through the esophagus, or taken away by repeated lavage, may be forced into the stomach, greatly dilating it, the bowel contents in these cases moving in the direction of least resistance. This is an important fact to remember in abdominal surgery, for lives may be saved by the repeated use of the stomach-pump, just as we may cure a patient with acute dilatation of the stomach, with apparent spasmodic contraction of the pyloric ring, and a loss of motility in the gastric muscle fibers.

While there may be shock in most cases of severe or fatal postoperative paralytic obstruction, this is the result of, and is associated with the absorption of bacterial toxic products from the bowel or the peritoneal cavity into the intestinal walls and tissues of the body. We have proof of this in the fact that when we remove the mechanical obstruction and allow the virulent poisonous contents above in the distended and paralytic bowel to pass onward, the patient may collapse from the rapid absorption in the comparatively healthy bowel below, the epithelial resistance being quickly impaired. It is further shown by the experiments of Ramzi, Kula, Clairmont and Albu, that the subcutaneous or intraperitoneal injection of the filtrate of normal intestinal contents gave nearly negative results, but that the injection of the filtrate from an obstructed and distended bowel caused serious or fatal symptoms, in some cases collapse being marked. The absorption of intestinal gas does not seem to have much effect on man in paralytic obstruction, and, as the bowel distends, the absorption of gas and liquid from the bowel is diminished, and finally ceases. In such cases, however, the absorption of bacteria or of toxic bacterial products from the bowel contents into the bowel walls and other tissues is increased, because of the injury to or destruction of the epithelial layer, through which it is probable bacteria can not pass while it is intact and normal. This absorption from intestinal contents, however, ceases, after death of the bowel. Postoperative peritonitis, which causes intestinal paralytic distention, or probably sometimes narrow constriction in some part of the bowel, is usually caused by the invasion of pathogenic bacteria or their toxic products from the gastrointestinal tract, the pelvic organs, or by infection through abdominal wounds, or by unclean abdominal operations; a frequent contributing cause is extensive intestinal exposure and rough manipulation of the stomach, intestines, peritoneum and mesentery. The rough manipulations of the intestines injure the endothelial layer, the nerve plexus and the mesenteric structures; and tension on the mesentery may result in increased inhibitory splanchnic impulses, thereby causing distention of the bowel by impairing or destroying its motility and peristalsis.

What I have said above and also what follows is intended to apply to both acute and subacute postoperative mechanical or paralytic intestinal obstruction, remembering that the complete mechanical form will

always become paralytic if the obstruction is not promptly removed by surgical intervention; hence it will be seen that mechanical obstruction is always surgical, but that with too much delay surgery is of no avail, for the bowel will then have become greatly distended with liquid and gas, which gradually interferes with the nutrition of its walls, destroying the epithelial barrier against bacterial invasion. Unfortunately we are often unable to distinguish between the early or even the late primary mechanical and the purely paralytic forms. While some surgeons have claimed that the differentiation can usually be made, this is contrary to the experience of nearly all abdominal surgeons of broad experience; for this reason it may be impossible to decide if an operation is necessary until it is too late to be of benefit. In such cases as can be diagnosed, however, the abdomen must be promptly opened, the obstructing cause, whatever it may be, removed when it is possible to do so, the surgeon operating rapidly and committing as little traumatism as possible, for these cases will not resist a long operation or rough handling of the intestines and other intra-abdominal structures. Such patients will often recover if operated on before there is much peritonitis or peritoneal infection, and before the bowel is so distended as to interfere with its circulation and nutrition until its vitality is destroyed by the bacteria and bacterial toxic products absorbed from the intestinal contents. In some cases in which the obstruction can be removed, and in all cases in which it can not for the time being be removed, we shall get better results by performing enterotomy or even enterostomy, so as to give immediate temporary or continued drainage of the bowel contents, thereby removing tension on the walls and lessening the absorption of toxic products, thus giving the bowel a better chance to regain its nutrition and motility. In such cases a subsequent operation may be performed to remove the obstruction and to restore the bowel attached to the abdominal wall to its normal condition.

In operations for postoperative intestinal obstruction, it may be better not to enter the abdomen through the original incision, but to select a point that will probably enable the operator to find and remove the obstruction with the least possible exposure and handling of the intestines; by this means he may avoid opening a wound, often infected, and protect the patient from further peritoneal infection from this source. In the absence of any evidence of the seat of the obstruction, it is better to enter the abdomen in the median line below the umbilicus, for through this opening the focus of trouble may be found more easily than through any other incision; but if the original opening was made in or near the median line, then it may be better to open the cavity through an incision in the outer border or beyond the right rectus in the region of the appendix. If, however, there is evidence that the trouble is in the sigmoid flexure from volvulus or intussusception, it would be better to open on the left side. By practically studying the anatomy of the jejunum, the ileum, the mesentery and the relative positions in the abdominal cavity of the first, second and third parts of the small intestine, so beautifully demonstrated by Monks, we may better understand the part of the bowel presenting, its direction, and how to handle it quickly with the least possible traumatism. While I have operated successfully in many cases for intestinal obstruction, with the abdomen distended, a recital of these cases would be of no practical value

and of no interest to the experienced abdominal surgeon. Unfortunately the tendency with many of us is to report a long series of successful operations, often omitting the underlying basic principles on which we are enabled to philosophize correctly. The best surgeon is he who combines a knowledge of embryology, anatomy, physiology, bacteriology, pathology, diagnosis and surgical technic, so as to enable him to reason logically as to what is best in the interest of the patient in any individual case; and, finally, he should be a surgical mechanic. There is no department of surgery to which this more fittingly applies than to the treatment of bowel obstruction from any cause. In true paralytic postoperative obstruction with no suppurative peritonitis, surgery is usually contraindicated; hence the treatment should be rather preventive than curative. In some cases apparently severe, we may have a few days of discomfort, even with pain, nausea, vomiting, obstruction and distention, followed by an uninterrupted recovery without treatment; but a severe toxemia or general peritonitis may develop, which may not improve either under medicinal or surgical treatment. Purgation is contraindicated, and no food should be given in the stomach. If liquid and gas are regurgitated into the stomach and not easily expelled, they should be promptly removed by a stomach-pump, and lavage frequently repeated. It must be remembered that repeated vomiting of small quantities indicates a dilated stomach, a condition similar to what is found in an overdistended bladder. At the same time water through the rectum must be supplied to the tissues and thirst controlled by slow introduction of saline solution after the fashion recommended and described by Murphy. Finally, if gas does not pass from the colon, enemas may be given, care being taken never to distend the bowel too much. In some cases it is possible that the addition of small quantities of alum or carminatives may stimulate peristalsis in the large bowel and cause the expulsion of liquid and gas, leaving the cecum and colon relatively empty, thus encouraging the passage of liquid and gas from the small intestine into the large bowel.

In operations for paralytic or mechanical obstruction with peritonitis, drainage with a rubber tube introduced to the bottom of the pelvis is indicated, and may aid in the elimination of poisonous products. In such cases it may be better to put the patient in the semi-sitting or nearly sitting posture, so as to encourage gravitation of peritoneal liquids into the pelvic cavity, whereby the absorption of bacterial toxic products is reduced to a minimum. Proctoclysis should also be used, putting in the rectum from ten to fifteen pints of saline in each twenty-four hours. In such cases, no food should be given by the stomach for several days or a week, and the patient should be given no solid food for ten days or two weeks. Milk in any form should not be considered a liquid food. After several days we may give nutritious enemas. Finally when gas is passing freely and the bowels can not be moved by enemas, castor oil may be given, but it is usually best not to give saline purgatives. The general belief that we should give remedies internally, subcutaneously or intravenously to establish intestinal peristalsis in paralytic obstruction has no scientific basis. Such treatment is positively contraindicated in cases in which there is peritonitis, inflammation of the intestinal walls or injury to the nerve plexus or muscles in the bowel walls, and may cause death of a patient who would otherwise have recovered. In peritonitis the intestines should be at rest to prevent

the diffusion of infection, and in inflammation of or injury to any part of the bowel wall, rest is essential to encourage repair and a return to the normal anatomic and physiologic condition; hence such remedies could be indicated only in cases in which the paralytic obstruction results from central inhibitory influences through the splanchnics, probably associated with control of the vagi motor impulses, and in which there is but little injury to the nerve plexuses and muscles of the bowel. But we may expect such patients to recover without medicinal treatment if we observe the suggestions above mentioned as to stomach lavage and the use of saline solutions in the colon, as conditions may indicate.

While the experimental work of Meltzer and Auer and other laboratory research investigators has done much to show what medicines influence the motility and the inhibition of the gastrointestinal tract, the results are far from complete, and from this work we have probably gained but little to aid us in the medicinal treatment of paralytic intestinal obstruction. Further research will probably give a clearer insight into the subject, and when we have developed a more correct knowledge of the etiology, the diagnosis and the pathology of paralytic intestinal obstruction, we may then obtain better results from medicinal treatment. We know that ergot causes contraction of the involuntary muscle fibers, and it seems to increase peristalsis, but it is so erratic in its action that it can not be depended on, and may sometimes, as shown by Meltzer and Auer, cause tetanic contractions similar to what may occur in the muscles of the uterus when given during labor or after the birth of the child. Atropin abolishes vagi motor impulses and impairs the spontaneous movements of the stomach and intestines and should not be given.

If a paralytic condition of the bowel is due solely to inhibitory impulses, then hypodermic administration of morphin may be indicated, but we have no means to decide this question. Eserin (physostigmin), hypodermically administered, will increase peristalsis in the healthy animal, but its effect is not lasting, and, while some surgeons have reported successful results from its use in paralytic obstruction, it has no claim for general acceptance; it may be given in doses of 1/40 to 1/60 grain, repeated when necessary to get its therapeutic effect, but never used to excess.

Resection of the devitalized intestine in paralytic obstruction, with the walls filled with bacteria and bacterial toxic products, is generally fatal, and is especially likely to be so if the involvement is extensive. If undertaken, the operation must be performed quickly with lateral anastomosis. The bowel should be crushed well above and below the dead part in healthy tissue and ligated with catgut in the crushed groove, the ends inverted and closed with a purse-string linen suture. The anastomotic opening should be three inches in length, and sutured as in gastroenterostomy, the inner suture of catgut introduced through all the walls, linen being used for the outer seroserosus suture. While it is theoretically preferable that all intestinal anastomosis should be made isoperistaltic, experience has taught that if this method is not observed, peristalsis will be established, but will be delayed in the anastomotic region. In obstruction from hernia or mesenteric thrombosis, where the devitalization of the bowel is not too extensive or shock not too profound, resection with lateral anastomosis is indicated. This does not mean that in all intestinal resections the union must be made by lateral anastomosis, for in many cases in which the trouble is not

acute and the resected ends are in a healthy condition, it may be better to make an end-to-end union, using the clamps for suturing, as we do in lateral anastomosis or in gastroenterostomy. Fortunately, postoperative paralytic or mechanical intestinal obstruction is now comparatively rare in the practice of a careful abdominal surgeon who rigidly observes asepsis in himself, his patients, assistants, nurses and everything that could convey infection, and who properly prepares his patients for operation. In cases in which immediate operation is not imperative, the bowels should be thoroughly moved by a large dose of castor oil, and nothing but liquid food given for two days before the operation, and no food the day of the operation. The intestines should be exposed and handled as little as possible, and the mesentery should not be put on the stretch; otherwise violent inhibitory impulses may be caused through the splanchnics, or peristaltic inhibition, because of traumatism to the nerve plexus or muscles in the bowel walls; such exposure and handling may also destroy much of the resistance in the endothelium of the peritoneum to the invasion of bacteria or bacterial toxic products, which causes peritonitis, local or general toxemia or septicemia. Drainage should be avoided, if possible, and when necessary a perforated or split rubber tube should be used, for bad postoperative results have often been caused by the use of the glass tube. Gauze ceases to drain after a few hours, and then is positively harmful; it should never be used in the peritoneal cavity except to control dangerous oozing of blood or to isolate an infected area. I have often seen in my own experience bad results from the use of gauze, and even when it is used to isolate an infected area the rubber tube may be also used.

I have recently had two cases of perforation of the stomach, in the first of which drainage by the tube alone was employed; in the second, drainage by the tube and gauze. The first patient made an uninterrupted recovery with practically a normal temperature and pulse, though the operation was performed nearly twenty-four hours after the perforation occurred. The second operation was performed seven hours after perforation, and, while the patient recovered and is now in vigorous health, there was decided suppuration, elevation of temperature and acceleration of pulse, which I believe would have been avoided had I not used gauze with the tube.

In conclusion, I beg to suggest that surgeons who are contributing something of value for the betterment of abdominal surgery should know the results of the research laboratory investigators of the gastrointestinal tract and the peritoneal cavity. They should be familiar with the results of the work of Pawlow and Starling and Bayless on the physiology, Metchnikoff and Herter on the bacteriology, Cannon, Murphy, Meltzer and Auer on the motility, Buxton on peritoneal absorption, Lennander on the sensibility of the intraperitoneal structures, and the laboratory research work of many other men who have done much in these related fields of science.

Retinal Hemorrhages and Vision.—P. Fridenberg, in *Ophthalmology*, April, 1903, states that the effect of retinal hemorrhages on vision depends largely on their extent and location. If extensive and central they may cause marked blindness. The remote results are rupture through the hyaloid with the formation of vitreous hemorrhages, proliferating retinitis, glaucoma, and detachment, all of which lead to complete blindness.

GASTRIC SYMPTOMS CONSEQUENT ON
ARTERIOSCLEROSIS *

HENRY L. AKIN, M.D.

OMAHA

Arteriosclerosis, while it may occur in comparatively young individuals who have an inherited tendency to this sort of trouble, syphilitic or otherwise, or who have become subject to it through an acquired syphilis, is pre-eminently a disease of the later years of life and the mention of it brings to our minds almost involuntarily the picture of an elderly person. And it is of a train of symptoms quite frequently to be encountered in persons of middle age having arterial degeneration that I wish to speak. I have been struck with the frequency with which the various manifestations of arteriosclerotic change in the chest and abdomen are attributed to the stomach and some primary disorder of digestion not only by the laity but by physicians as well, and in view of that fact have thought that it would be a profitable subject to bring to consideration.

The group of symptoms must be one very strongly suggesting that the seat of the trouble is in the stomach, not only because it quite frequently deceives the physician who handles the case, but because it has generally fixed this idea so strongly on the patient's mind that even after a careful examination and the eliciting of facts which make it certain that the vascular system is the one at fault, he can never be fully convinced that the primary trouble is not in the stomach, and keeps harking back to that idea all the time and insisting that, if the stomach were put in good condition, he would be entirely well again.

HISTORIES OF CASES

Perhaps I can not do better than to cite a few case histories here, and then we can see in what form such cases present themselves and why they so often lead to a mistaken diagnosis.

CASE 1.—History.—The patient, E. C., an Englishman, aged 54, was a stockman. His health had been rugged all his life until January, 1906, when he "began to have trouble with his stomach." He habitually ate two meals a day—no breakfast, but a hearty dinner and good supper—and his trouble was something like this: In the morning he felt well, but after dinner if he went out and walked a quarter or half a mile there came on him a feeling of fullness in the epigastrium, a pain under the ensiform cartilage, running down the left arm; he felt oppressed, as if he could not get his breath and must stop for a time; on stopping he would soon get rid of considerable gas by belching, after which he felt well and could go on with no further trouble. If he sat still for half an hour or so after eating he generally had none of this trouble. The same thing occurred again after supper, except that he more frequently remained quiet then. If he drank much fluid with his meals, especially ice-water or tea, he was almost certain to have an attack. He had no sour stomach, heartburn, water-brash or belching except as stated. He slept well and weighed 190 pounds; his bowels were regular. He was a hearty meat-eater; smoked and drank liquor occasionally. Twenty years ago, before coming to the United States, he was subject to gout and would have attacks of it about every six months.

Examination.—Large man, heavy-set, with ruddy complexion, the picture of health. Heart not enlarged, apex normal, mitral first sound not clear, aortic second sound sharply accentuated, no murmurs audible; pulse 90, apparently high tension. Stomach contents, free hydrochloric acid, 20; total acidity, 35. Urine, 1.016 acid. Thin ring of albumin, no casts.

Course of Disease.—This was the first case of the kind which had come to my attention, and I mistook it entirely,

paying all my attention to the gastric symptoms. Three meals a day, a restriction of food and meat, careful mastication, no alcohol or tobacco, relief from business and some medication helped very noticeably to relieve the patient, but relief was not permanent, so that shift was made from one thing to another until a typical angina attack disclosed the true nature of the trouble.

CASE 2.—History.—The patient, G. P., a farmer, aged 55, was always well with the exception of occasional attacks of rheumatism until within a year of his present illness. Some seven or eight months before the first examination he began to have "trouble with his stomach;" would feel all right during the forenoon and afternoon, but after supper, no matter how little he ate, he had distress. The stomach filled up with gas so that the patient felt full there, and had a sense of oppression in the chest and a feeling of anxiety for himself, such that he could not lie down, flashes of heat would shoot over his body; he could not sleep and sometimes the condition rose to the height of mild delirium or terrors of one sort or another. Belching up of gas brought immediate relief, which might remain for the night or be followed by another accumulation. This had been going on for months; the patient had been seen and treated for stomach trouble by all the local physicians, then by physicians from a neighboring town, really excellent practitioners, too, with carbolic acid, bismuth and pepsin to allay the fermentation and finally by a consultant from St. Joseph, Mo., who diagnosed the case as dilatation of the stomach (probably without a sufficiently careful physical examination), and prescribed certain stimulants and digestants and dietary regulation, all of which resulted in no benefit whatever.

Examination.—This revealed a double murmur at the aortic valve, evidences of an enlarged and roughened ascending arch, and along with this arteriosclerotic changes throughout the body, and thus the real source of the difficulties in the stomach were explained.

Course of Disease.—Treatment by rest, vasodilators, followed by potassium iodid, and some suggestions as to diet, gave an excellent result, and the patient obtained more relief than he had ever had from the local measures directed toward the stomach. This patient, though a fairly intelligent man, persisted in the belief that the real seat of the difficulty was in the digestive organs and, though driven to accept the fact that there might be something the matter with his heart, too, centered most of his hope on "some medicine to help out his stomach."

CASE 3.—History.—The patient, a business man, aged 62, had been all his life a sufferer from "dyspepsia;" that is, at times, gaseous distention of the stomach with nervousness and general distress, but of late years this condition had come on more frequently and grown much more serious. In his severe attacks the stomach was much enlarged—as his attending physician said, "almost to the extent of an acute dilatation," and most of this enlargement took place in an upward direction, thus by pressure greatly increasing the already existing cardiac distress. These attacks and lighter ones also were accompanied by extreme nervousness, fright and a feeling of great anxiety, and a cold sweat broke out over the whole body. Great care had to be taken with the evening meal, lest some food be taken which would more easily give rise to gas formation, and even in spite of the very best efforts this would occur at times. Three years before I saw the patient a new symptom developed, pain in the chest when walking in the cold or up-hill, and a few weeks before I saw him a serious angina seizure. Through it all the patient and his wife believed that the trouble was due to the stomach, and I was called to see if I could not make some suggestions as to diet which would afford relief. The arteries were hard and sclerotic, arterial tension high and a suspicion of an aortic systolic murmur was heard over the aortic area.

Course of Disease.—While some attention was paid to the diet to see that sufficient nutritious food was given to maintain physical strength, the efforts in medication were entirely directed toward relief of the vascular trouble and with very satisfactory results so far, now nearly three years.

* Read before the Omaha-Douglas County Medical Society.

the diffusion of infection, and in inflammation of or injury to any part of the bowel wall, rest is essential to encourage repair and a return to the normal anatomic and physiologic condition; hence such remedies could be indicated only in cases in which the paralytic obstruction results from central inhibitory influences through the splanchnics, probably associated with control of the vagi motor impulses, and in which there is but little injury to the nerve plexuses and muscles of the bowel. But we may expect such patients to recover without medicinal treatment if we observe the suggestions above mentioned as to stomach lavage and the use of saline solutions in the colon, as conditions may indicate.

While the experimental work of Meltzer and Auer and other laboratory research investigators has done much to show what medicines influence the motility and the inhibition of the gastrointestinal tract, the results are far from complete, and from this work we have probably gained but little to aid us in the medicinal treatment of paralytic intestinal obstruction. Further research will probably give a clearer insight into the subject, and when we have developed a more correct knowledge of the etiology, the diagnosis and the pathology of paralytic intestinal obstruction, we may then obtain better results from medicinal treatment. We know that ergot causes contraction of the involuntary muscle fibers, and it seems to increase peristalsis, but it is so erratic in its action that it can not be depended on, and may sometimes, as shown by Meltzer and Auer, cause tetanic contractions similar to what may occur in the muscles of the uterus when given during labor or after the birth of the child. Atropin abolishes vagi motor impulses and impairs the spontaneous movements of the stomach and intestines and should not be given.

If a paralytic condition of the bowel is due solely to inhibitory impulses, then hypodermic administration of morphin may be indicated, but we have no means to decide this question. Eserin (physostigmin), hypodermically administered, will increase peristalsis in the healthy animal, but its effect is not lasting, and, while some surgeons have reported successful results from its use in paralytic obstruction, it has no claim for general acceptance; it may be given in doses of 1/40 to 1/60 grain, repeated when necessary to get its therapeutic effect, but never used to excess.

Resection of the devitalized intestine in paralytic obstruction, with the walls filled with bacteria and bacterial toxic products, is generally fatal, and is especially likely to be so if the involvement is extensive. If undertaken, the operation must be performed quickly with lateral anastomosis. The bowel should be crushed well above and below the dead part in healthy tissue and ligated with catgut in the crushed groove, the ends inverted and closed with a purse-string linen suture. The anastomotic opening should be three inches in length, and sutured as in gastroenterostomy, the inner suture of catgut introduced through all the walls, linen being used for the outer seroserosus suture. While it is theoretically preferable that all intestinal anastomosis should be made isoperistaltic, experience has taught that if this method is not observed, peristalsis will be established, but will be delayed in the anastomotic region. In obstruction from hernia or mesenteric thrombosis, where the devitalization of the bowel is not too extensive or shock not too profound, resection with lateral anastomosis is indicated. This does not mean that in all intestinal resections the union must be made by lateral anastomosis, for in many cases in which the trouble is not

acute and the resected ends are in a healthy condition, it may be better to make an end-to-end union, using the clamps for suturing, as we do in lateral anastomosis or in gastroenterostomy. Fortunately, postoperative paralytic or mechanical intestinal obstruction is now comparatively rare in the practice of a careful abdominal surgeon who rigidly observes asepsis in himself, his patients, assistants, nurses and everything that could convey infection, and who properly prepares his patients for operation. In cases in which immediate operation is not imperative, the bowels should be thoroughly moved by a large dose of castor oil, and nothing but liquid food given for two days before the operation, and no food the day of the operation. The intestines should be exposed and handled as little as possible, and the mesentery should not be put on the stretch; otherwise violent inhibitory impulses may be caused through the splanchnics, or peristaltic inhibition, because of traumatism to the nerve plexus or muscles in the bowel walls; such exposure and handling may also destroy much of the resistance in the endothelium of the peritoneum to the invasion of bacteria or bacterial toxic products, which causes peritonitis, local or general toxemia or septicemia. Drainage should be avoided, if possible, and when necessary a perforated or split rubber tube should be used, for bad postoperative results have often been caused by the use of the glass tube. Gauze ceases to drain after a few hours, and then is positively harmful; it should never be used in the peritoneal cavity except to control dangerous oozing of blood or to isolate an infected area. I have often seen in my own experience bad results from the use of gauze, and even when it is used to isolate an infected area the rubber tube may be also used.

I have recently had two cases of perforation of the stomach, in the first of which drainage by the tube alone was employed: in the second, drainage by the tube and gauze. The first patient made an uninterrupted recovery with practically a normal temperature and pulse, though the operation was performed nearly twenty-four hours after the perforation occurred. The second operation was performed seven hours after perforation, and, while the patient recovered and is now in vigorous health, there was decided suppuration, elevation of temperature and acceleration of pulse, which I believe would have been avoided had I not used gauze with the tube.

In conclusion, I beg to suggest that surgeons who are contributing something of value for the betterment of abdominal surgery should know the results of the research laboratory investigators of the gastrointestinal tract and the peritoneal cavity. They should be familiar with the results of the work of Pawlow and Starling and Bayless on the physiology, Metchnikoff and Herter on the bacteriology, Cannon, Murphy, Meltzer and Auer on the motility, Buxton on peritoneal absorption, Lennander on the sensibility of the intraperitoneal structures, and the laboratory research work of many other men who have done much in these related fields of science.

Retinal Hemorrhages and Vision.—P. Fridenberg, in *Ophthalmology*, April, 1909, states that the effect of retinal hemorrhages on vision depends largely on their extent and location. If extensive and central they may cause marked blindness. The remote results are rupture through the hyaloid with the formation of vitreous hemorrhages, proliferating retinitis, glaucoma, and detachment, all of which lead to complete blindness.

but also with their secretion and absorption as well; this would apply as well to the stomach, and the atony and fermentation resulting therefrom admirably explain the cause of the distention, belching and distress in the stomach so prominent in all these cases.

The variety of ways in which these arteriosclerotic changes may manifest themselves is great and sometimes leads to considerable confusion in the establishing of a diagnosis, as for instance, the pain and tenderness in the epigastrium if combined with vomiting and backache, may closely simulate gastric ulcer and when combined with hematemesis, which is not so very infrequent in abdominal arteriosclerosis, the differentiation is well-nigh impossible under continued observation. Perutz of Munich in a recent article² on abdominal arteriosclerosis cites a case in which he had great difficulty to exclude carcinoma of the stomach. It is as follows:

CASE 5.—Patient.—A woman, aged 59, who had always done hard work, but who had, nevertheless, always been well till some few weeks before examination, when she was taken with loss of appetite, distressing fulness after eating and increasing weakness.

Examination.—The patient was prematurely aged, pale and feeble, the heart boundaries were normal, the pulse regular, 66 to 72. Through the relaxed abdominal walls no swelling could be felt, but on palpation the abdominal aorta was sensitive to pressure. After nearly every meal the patient complained of distention of the stomach, and the feeling of pressure associated with this extended upward into the throat. Belching relieved the distention. Sometimes the latter was so great that the patient was obliged to leave her bed in order to get her breath. Lately these attacks had come on between meals and also at night. The heart "almost ran away" at these times. Once after such an attack there was irregular pulse. Repeated examinations of the circulatory system in the intervals were without result. There was no occult blood in the stool.

Course of Disease.—All dietetic and medicinal treatment directed towards the stomach was without effect. On trial of diuretin there appeared in a short time a striking improvement. The patient reported that for several days she had scarcely had an attack; she was able to leave her bed and attend to the housework; her appetite was improved. From time to time she had attacks more or less severe, which, however, were always quickly improved through alternation of theobromin, digitalis or nitroglycerin.

To this I can add a report of a case which even more closely resembles cancer of the stomach than that of Perutz and which showed some very curious symptoms:

CASE 6.—History.—The patient, J. W., aged 60, a farmer, with tuberculous family history, had been a steady hard worker for years, during which time his health had been good, with the exception of an increasing tendency toward constipation during the last ten years. In January, 1907, just previous to the beginning of his present illness, he weighed 190 pounds. At this time he had an acute illness which lasted some weeks and he was never well thereafter. The symptoms at that time consisted of pain in the left side, passage of dark urine, together with marked weakness and loss of strength. These subsided in a month or six weeks, but the bowels grew more obstinately constipated. The patient's appetite was greatly affected, and he was unable to do any work. Lately he developed a pain in the back and a great deal of distress after eating. There was a feeling of weight or pressure in the stomach and this was soon followed by a peculiar train of symptoms. There was a sensation of heat all over his body, accompanied by profuse sweating, and later a chilly condition; the hands and feet were cold and damp and clammy; the pulse jumped from 45 or 46 to 100-104; there was some dyspnea and panting respiration; the patient was obliged to

lie down and cover up. This lasted thirty to forty minutes and he obtained relief gradually. In six months he lost sixty pounds; he had a great distaste for meat and a poor appetite generally. There was occasional vomiting.

Examination.—There was tenderness in the median line of the epigastrium, which was found to follow the course of the aorta, and was especially marked at and just above the navel. The heart was slightly enlarged to the left; there was no murmur, but a sharply accentuated aortic second sound. The arteries were generally stiff and hard, especially the brachial, which was hard and rolled under the fingers like a piece of rubber tubing; it was also tortuous; the pulse in the dorsalis pedis arteries was absent on one side, and the feet and legs were cold. Careful examination for possible malignant growth disclosed no further evidences of same and diagnosis was made of general arteriosclerosis.

Course of Disease.—The patient received frequent small feedings which did away with the symptoms of arterial spasm which had previously troubled him. He was put on small doses of iodids and as the arterial tension was low (112 mg. of mercury) he was given digitalis. Under this regimen he continued to improve considerably and was sent home with instructions to keep it up and to take particular care of himself afterward.

This case was referred to me for investigation because it had been thought to be a malignant condition on account of the rapid loss of weight, the distress after meals, etc. Arteriosclerosis, however, when it comes to a breakdown, as in this case, can be followed by very severe wasting process, and the disturbance after meals was clearly of vascular origin.

DIAGNOSIS

In the matter of diagnosis, it is of the utmost importance not to be led astray by the complaints of the patient as to indigestion, pain in the stomach, distention and belching, and so neglect to obtain a full history and make such a careful physical examination as will reveal the deeper causes of which these digestive troubles are only symptoms. It is not that the diagnosis is in itself so very difficult, but rather that the case presents a picture which the physician has not learned to recognize; though after he has seen and recognized one case, he learns to look for the rest of the chain of symptoms as I have presented them here. In the light of my present experience, it seems remarkable to me that I did not recognize more completely the conditions in my first case, but, at the time, the real cause was overlooked. It seems, then, that the most necessary thing is to call the attention of physicians to the relative frequency of such cases and to urge them to look further than the stomach when they have a patient past middle life complaining of pain in the stomach, distention after eating if he attempts any physical exertion, and dyspnea, relieved by belching of gas; especially when nocturnal seizures, accompanied by distention, heart disturbances dyspnea and great anxiety, are the prominent symptoms. Then an examination of the vascular system will usually clear up the matter entirely. A heart somewhat enlarged, an aortic second sound sharp and snapping, a murmur over the aortic area and rough sounds over the aorta itself, pulsation in the episternal notch, hardened arteries with usually a pulse of high tension, attacks of pain over the heart region radiating to the arm, marked tenderness over the abdominal aorta down to the navel, urine perhaps increased in amount or containing albumin in small quantity, or both increased and albuminous, all these point unmistakably to the circulatory system as the real cause of the trouble at hand.

2. München, med. Wchnschr., May 28 and June 4, 1907.

Such cases are quite similar in the underlying factor of disease, yet they vary sufficiently in their detail to allow them to be divided off into rough classes or groups. For instance, cases 2 and 3 illustrate a type in which all the attention is drawn to the stomach and its supposed misbehavior; most of the trouble comes on at night after the patient has gone to bed, and consists in gaseous distention, pressure upwards on the diaphragm, with still further embarrassment of the laboring heart, extreme nervous distress and anxiety, and at times delirium. Relief is immediate if the patient can belch up the gas accumulated, but this may be only temporary. It is really not surprising, in view of the apparent localization of all the symptoms that the patient should feel that the stomach is entirely at fault and direct his efforts toward improving its function, but the physician who runs across such a symptom-complex will do well to look deeper than the surface and seek some underlying cause for it.

In these two cases there is no hint of any muscular element; that is, the attack comes on almost invariably while the patient is at rest, but in Case 1, the physical effort was the exciting factor without which the trouble did not come on, yet the symptoms when they did appear, still, on the surface at least, incriminated the stomach as the chief offender—pain in the epigastrium, a feeling of fulness and distention there, and immediate relief on gaseous eructation.

Another case will illustrate this type still further.

CASE 4.—The patient, Mr. G., aged 63, an Englishman, twenty-five years ago had much trouble with rheumatism and still felt it in his fingers, ankles and feet. Otherwise he had always been well till the last three years. If he went outside after meals and walked or tried to do work of any sort, especially pump water, he was seized with a pain over the lower part of the chest and epigastrium, panted and felt oppressed and was obliged to desist from such effort. He had been treated for some time with stomachics, pepsin and similar medicines, which did not avail, the reason being apparent on physical examination, which showed the heart slightly enlarged to the right and to the left, systolic mitral and aortic murmurs, arteries hardened, tension high.

In these and many other similar cases we have a condition in which the real cause lies in the extensive involvement and serious degeneration of the organs and vessels of one great system, the vascular, while its effects, or at least its most striking and most easily perceived effects are manifested in various ways on another system, the digestive. For not alone is the stomach affected in this class of cases but also the whole of the intestinal tract, in ways even more varied and of quite as much intensity as those we are here considering; and it will no doubt prove to be an instructive and very fruitful quest to endeavor to elicit some of the reasons for this play of symptoms in the abdominal viscera. We are indebted for much of our work in this field to the observations and investigations to such men as Pal, Ortner, Buch, Perutz, Huchard and others, and an examination of some of their work and theories will be of benefit in throwing a light on the question at hand.

Ortner's contribution is the painstaking report of a case of general arteriosclerosis involving especially the superior and inferior mesenteric arteries and through them the intestines¹; and an exhaustive review of the literature pertaining to this subject. The symptoms in

his case had to do largely with the intestines and consisted of severe pains around and below the navel coming on two or three hours after eating, extreme distention with gas, difficulty in breathing, explosive belching, etc. The colon ascendens and transversum were greatly distended and visible through the abdominal wall but there was no sign of peristaltic waves. The severity of the attack was such as completely to incapacitate the patient.

All this Ortner explains on the basis of the anatomico-pathologic findings. The aorta was thickened and calcified, there was a thick deposit of lime salts about the mouths of its branches, especially the mesenteric arteries, and the small branches of these were stiff, inelastic and probably contracted. The result of this was that the intestines did not receive a sufficient quantity of blood from the aorta through the mesenteric arteries and what did come to them was poorly distributed, owing to the changes in the arterioles. The intestinal walls were poorly nourished; the muscular coat, weak and inefficient, was unequal to the task of doing its work, and this showed itself two to three hours after eating, when the intestines began to be called on to carry out their part in digestion, in disturbance of the motility and probably of the secretory and absorptive functions even to such an extreme degree as his case manifested; so that Ortner says that he could not help but be greatly impressed with the similarity which the condition in the intestines presented to that of intermittent claudication in the extremities, which latter he believes to be the result of a narrowing of the arteries and arterioles producing an ischemia of the muscles and consequent poor nourishment and an irritation of the nerve branches to the joints and muscles of the leg.

I do not know of any case in which the symptoms were predominant in the stomach as in those of my series, which has been as carefully worked out as Ortner, but we do know that the arteries supplying the stomach are in no way exempt from arteriosclerotic degeneration and that round ulcer has frequently been seen as a result of the trophic disturbances produced by arteriosclerosis and with all the conditions similar and the resulting symptoms almost the exact counterpart of those produced in the intestine.

I do not think we shall go far astray in assuming that the same causes produce similar symptoms in the one place as in the other, and that the gaseous distention, the belching, the oppression and the nervous phenomena resulting from these conditions are due to impaired motility and secretion, inability of the stomach properly to perform its natural function, resulting from ischemia of the stomach walls produced by the degenerated arteries and their branches.

To the working of these factors, especially in cases in which there is epigastric pain associated with the attacks, Buch adds an irritated condition of the abdominal sympathetic nerves as an important factor in exciting and increasing the distress of this class of patients. In this belief he is joined by Pal, whose researches in this field are very extensive; and as final additional causes both authors are inclined to consider vessel spasm, overaction of the vasoconstrictors due to irritants such as lead, caffeine, autotoxemia and possibly nicotine as bearing a not inconsiderable part in the production of the distressing symptoms.

Pal says further that it is his belief that the interruption of the normal supply of arterial blood to the intestines interferes not only with their motility

1. Zur Klinik der Angiosklerose der Darmarterien (Dyspragie intermittens angiosclerotica intestinalis), Samml. klin. Vortr. (Volkmann's), No. 347.

cholelithiasis or the concomitant cholecystitis and cholangitis incident thereto or provocative thereof. It was further shown that, at a certain stage in its progress, chronic pancreatitis becomes an incurable disease or, by extension of the inflammatory process, produces irremediable changes in the islands of Langerhans, with a resulting pancreatic diabetes. If we can so allay our surgical consciences as to ignore the impending dangers of incurable inflammatory changes in the wall of the gall bladder necessitating a cholecystectomy; of obstructive changes in the cystic duct eliminating the gall bladder from the biliary circuit; of crippling pericholecystic adhesions; of suppurative cholecystitis and cholangitis; of perforation of the gall bladder—some one of which is an ever-present danger in every case of gallstones—in the light of our present knowledge of pancreatic disease, we no longer can fail to appreciate the probabilities of an incurable pancreatitis or the possibilities of a fatal diabetes.

That pancreatitis can be caused by the mechanical obstruction of the excretory duct of the pancreas by a calculus lodged in the common bile duct, or in the ampulla of Vater, or by extension of infection from the biliary channels, will be appreciated readily by reference to the results of animal experimentation and to the anatomic relations existing between the common bile duct and the head of the pancreas.

The common duct passing through the gastrohepatic omentum, from its origin by the union of the cystic and common hepatic ducts, runs behind the first portion of the duodenum and enters the head of the pancreas, where, in the majority of instances, it forms a junction with the duct of Wirsung, the principal and most constant excretory duct of the pancreas, and together, through a common channel, the diverticulum of Vater, they open into the duodenum. In practically two-thirds of all individuals the common duct, in its course through the pancreas, runs in a canal in the head of that organ completely covered by pancreatic tissue, while in the remaining one-third it traverses a groove on the posterior surface of the head of the pancreas, and is not covered over by glandular structures. Occasionally the duct of Wirsung empties into the common duct some distance above the opening of the latter into the duodenum, and, again, the common duct and the duct of Wirsung fail to effect a junction in the head of the pancreas, but pass on to the duodenum, where they open by separate but contiguous openings.

It has been shown by animal experimentation that the injection of either pure bile, or of bile mixed with mucus, into the pancreatic duct will cause a pancreatitis, the intensity of the inflammation depending on the concentration or dilution of the bile. The blocking of the duodenal outlet of the ampulla of Vater by a small gallstone, as in the case reported by Opie, necessitates a retrojection of bile into the pancreatic ducts. When the common bile duct and the pancreatic duct unite to form a common channel some distance before opening into the duodenum, this same diversion of the bile stream into the pancreas must occur whenever a gallstone becomes impacted in this common channel.

Opie has shown that the injection of pure or undiluted bile into the pancreas causes an acute pancreatitis, while Flexner has demonstrated that the injection of bile containing a large increment of mucus results in a chronic pancreatitis. While the retrojection of bile into the pancreas must be looked on as necessarily an infrequent cause of pancreatitis, the prevalence of chole-

cystitis in gallstone disease, with an increased outpouring of mucus, thereby diluting the bile, undoubtedly accounts in a measure for the greater prevalence of chronic pancreatitis, as compared with the acute form. Anatomic conditions, however, will not permit the retrojection of bile except in a very small proportion of individuals.

It is in the obstruction of the duct of Wirsung by the pressure of a gallstone lodged in the pancreatic portion of the common duct, or in the ampulla of Vater, that gallstones become of such great etiologic importance in pancreatitis. As a result of the calculous obstruction, the pancreatic fluid, dammed up in the pancreas, overdistends the walls of the pancreatic duct and renders them less resistant to bacterial infection. Infection extending from the bile tract, either directly by continuity of tissue or indirectly through the lymphatics from the gall bladder to the head of the pancreas, readily infects the imprisoned fluid, the distended ducts and the glandular tissues themselves, and a chronic pancreatitis results.

Practically 80 per cent. of the cases of pancreatitis are but terminal events in the course of gallstone disease and its associated infections. It has been established that pancreatitis, occurring in the acute form, may quickly prove fatal, and in the chronic form may lead to a long period of invalidism, eventually terminating in death. Further, the operative results obtained by many surgeons prove that, in the majority of instances, chronic pancreatitis may be cured by the removal of the offending gallstones and the subsequent temporary or permanent drainage of the biliary tract. At what point in the progress of chronic pancreatitis biliary drainage may fail as a curative agent is not established. Neither can it be determined which particular case of gallstone disease will terminate in pancreatitis, nor at what stage of the former the latter will occur.

Routine postmortem examinations have shown that from 6 to 10 per cent. of all patients dying in public hospitals have gallstones. The higher percentage was observed in Germany and was based on the examination of 10,866 bodies. The percentage incidence in England and America is lower than in Germany and is practically the same for the two countries, being about 7 per cent. That but a small proportion of the cases of gallstone disease has been recognized as such during life must, of necessity, explain the great discrepancy between the relative number of diagnoses of gallstones and these postmortem findings. Many unhesitatingly question the accuracy of these results of postmortem examinations as to the frequency of gallstones, because of the fact that they do not tally with their non-operative observations on the living subject. The fact must not be obscured, however, that a positive finding is of far more value than an unsupported negative opinion.

Unquestionably but a minority of the patients afflicted with gallstones suffer from the disastrous terminal events thereof, and consequently few present the pronounced symptoms demanded by our text-books and by many of our surgeons as necessary before a diagnosis is warranted. On the other hand, cases of so-called "indigestion," "dyspepsia," "gastralgia" and "biliousness" are as common as the sands of the sea. In the light of to-day's knowledge, it seems fair to hold that in the great majority of instances these cases of indigestion, of dyspepsia, of ill-defined stomach disease, of biliousness, are, in very fact, cases of gallstone disease giving rise, not to the decided symptoms of terminal

TREATMENT

The treatment (for a time at least) often gives quite satisfactory results. The diet should be restricted to plain, nutritious and digestible food, the evening meal very strictly limited, so as to leave no chance for gas formation, and careful attention paid to such hygienic aids as are suitable to the case—bathing, fresh air, suitable exercise, attention to the bowels, relief from work, etc. The results obtained from the use of drugs in these conditions is, as a rule, very satisfactory, and foremost among these stand the vasodilators, diuretin, a saturated solution of sodium nitrite and nitroglycerin. Diuretin, or theobromin sodiosalicylate, is the most effective and most used, being employed in doses of ten to fifteen grains three times a day. So prompt and satisfactory is its action in cases of this kind that its use has been recommended as a means of diagnosis in doubtful cases; just as we use quinin in suspected malaria and mercury in syphilis; the case cited by Perutz is a good example of this. Its effect, as well as that of the others mentioned, depends on its powerful action in overcoming the vessel spasm and dilating the arterioles so that they allow a greater flow of blood to the sclerosed areas. Of diuretin it is also suggested by Buch that it may neutralize the effect of some toxic agent which tends to irritate the vasomotor centers and cause contraction. Whatever the exact mode of action, its effects are very satisfactory, and its use may be continued for one or two weeks or even longer without harm. Following this the effect may be continued by the use of tincture of strophanthus, five to eight drops three times a day, which seems to have a similar action to the diuretin, so much so that it is used in place of the latter in some cases in which expense is a great consideration.

As in all arteriosclerotic conditions, the iodids have an important place. Potassium or sodium iodid in doses of five to ten grains may be continued over a long period, but it is asserted that the good they accomplish is not due so much to their so-called alterative effects, as it is either to a dilating effect on the vessels involved or to a lessening of the blood density; as to this I can not say.

403 McCague Building.

Delayed Death in Gunshot Wound of Heart.—A remarkable instance of delayed death in gunshot wound of the heart is narrated by Dr. R. S. Magee, in the *Journal of the Kansas Medical Society* for April. A colored man, 18 years of age, was shot in the left heart at close range with a shot gun. The victim turned and walked away into the street and then dropped dead, clasping his own gun firmly in his hand. The distance walked by the man after being shot was, by the coroner's measurement, 41 feet. Yet it was found on post-mortem examination that there was "a circular (punchlike) opening, two and one-half inches in diameter, just above and including the left nipple. The fifth rib was broken. The pericardium was torn away and in shreds. The left ventricle was split in two from base to apex, separating it from the interventricular septum completely. Two openings admitting the index finger tip were found in the septum, passing through into the right ventricle. The right ventricular walls were otherwise uninjured. A number of shot, together with one of the gun wads, were found in the muscular substances of the heart. Some shot were found in the base of the left lung, the remainder in the bottom of the left pleural cavity, which also contained several pints of uncoagulated blood. All of the charge passed through the opening in the chest wall, as no shot were found in the skin outside, about the opening."

CHOLELITHIASIS AND PANCREATITIS: THEIR EARLY RECOGNITION *

CHARLES N. SMITH, M.D.

Gynecologist to St. Vincent's Hospital
TOLEDO, OHIO

The prevalence of cholelithiasis and of infections of the bile tract, as the essential etiologic factors in the production of the great majority of the cases of pancreatitis, demands most thoughtful consideration, as must the fact that pancreatitis, in itself, may become an incurable condition or, by extension of the inflammatory process to the islands of Langerhans, result in a fatal diabetes. The general recognition of these now well-established facts by the profession should lead, not alone to the surgical removal of gallstones in every instance, but, as well, to the performance of the necessary operation at the earliest possible moment, before opportunity is given for the secondary involvement of the pancreas, as a prophylactic measure aimed against a probable pancreatitis and a possible diabetes. If we are to operate successfully on the gall tract, not alone for the prevention of the serious terminal events in that tract depending on inflammation or calculi, but also with the object of forestalling a secondary pancreatitis and a diabetes, we must forever eliminate that ancient and erroneous belief that gallstones may remain in the gall bladder or the ducts for a long and indefinite period, unproductive of symptoms and innocuous as to results. We must go further than this and, improving our diagnostic methods, determine the existence of gallstones at a much earlier period than is now customary.

A complete and revolutionary revision of our knowledge of the symptomatology of gallstone disease is about due—is, in fact, now under way. In the past, as in the present, we have considered as indicative of gallstone disease the terminal symptoms resulting from the complications and sequels of the disease and not the early symptoms of the uncomplicated disease itself. The long-continued presence of gallstones gives rise to certain pathologic conditions and their attendant train of symptoms as, for instance, severe and repeated attacks of biliary colic; impaction of stone in the common duct with or without intermittent jaundice and acholic stools; occlusion of the cystic duct with hydrops of the gall bladder; and we are wont to look on these and other late results and their symptoms as the symptoms of gallstones. Loss in weight is often mentioned as a symptom of gallstone disease, while, properly considered, it is in no sense a symptom of gallstones, but is a symptom, or result rather, of either a pancreatitis or of a suppurative infection of the biliary tract, either one of which is but a late secondary condition arising from the presence of gallstones. Too long and too frequently have we congratulated ourselves on our ability in the diagnosis of gallstones, with the diagnosis based on such late and apparent conditions, when, as a matter of fact, we have failed completely in the recognition and interpretation of the early, or inaugural, symptoms of the disease and recognized only the late and terminal symptoms of the complications and sequels.

As referred to in a previous writing,¹ it has been shown that practically 80 per cent. of the cases of pancreatitis have occurred secondary to, or associated with,

* Read before the Erie County (Ohio) Medical Society, March 24, 1909.

1. Smith, C. N.: The Surgical Conception of Pancreatitis, *Ann. Surg.*, June, 1909.

while the remaining third seemed thicker, less supple and was of a decided grayish color. The gall bladder contained a mixed bile and mucus, black, thick andropy, and a quantity of small, soft, sand-like particles. These were the foundation-stones of gallstones yet to be builded.

A valuable symptom, when present, is tenderness on pressure over the posterior surface of the liver, in an area extending from the eleventh dorsal to the first lumbar vertebra, and laterally from a line one inch to the right of the vertebral spines to the posterior axillary line. Tenderness in this area of Boas is present in some cases in which there is absence of tenderness over the gall bladder itself.

The fact must be recognized that the early symptoms ascribed to gallstones are but the symptoms of the inflammation which their presence has provoked. Gallstones lying in the gall bladder, producing or aggravating a cholecystitis, are attended by the general symptoms of the latter and not by any special symptoms attributable to the gallstones themselves, so long as they remain quietly sequestered. A mild degree of inflammation of the gall bladder, however, attended by a varying amount of desquamation of epithelium, the "lithogenous catarrh" of Meckel, is a necessary etiologic condition in gallstone disease. Operation based on the early symptoms under consideration—the symptoms of cholecystitis—may disclose a cholecystitis, but no gallstones. The cholecystitis so found may be the precursor of gallstone formation, or the result thereof, the gallstones at one time present in the latter instance having escaped through the ducts into the intestine and thence from the body.

A history of "malarial fever" in connection with, or subsequent to, or even antedating, these inaugural symptoms, should be critically analyzed in every instance. It will frequently develop that the chills of the supposed malarial fever occurred, not with any regularity, but with decided irregularity. My patients report these chills as occurring once or twice in a given day, then recurring after an interval of from two days to a week, then perhaps daily for a few days, with a subsequent lapse of days between attacks. The chills are followed by fever and sweating. One patient reports these chills, irregular in occurrence, extending over a period of four months, followed by two weeks of profound jaundice, and by four years of indigestion, flatulence, oppression and weight in the stomach after meals. These irregularly recurring chills which are so readily mistaken by the careless observer for the evidences of malarial fever are in reality the symptoms of decided infection of the bile tract or of calculous obstruction of the common duct. Moynihan has called attention to the "steep" form of temperature curve occurring in acute infections of the biliary tract and in cases of stone passing through the common duct. The temperature rapidly rises to 102, 103 or 105, or even above, and as rapidly falls to normal or below. This rapid rise and fall recurs repeatedly but irregularly.

One young man who recently consulted me gave a history of "ague" extending over a period of two years, with an irritable hacking cough unattended by expectoration, with stabbing pain at the base of the right lung on deep inspiration. During these two years he complained of indigestion, belching, nausea and occasional vomiting. There was a feeling of fulness in the head, of vertigo and of drowsiness. The skin had a peculiar and striking bronzed appearance and yet the

patient was insistent in the statement that he had never been jaundiced. There never had been an attack of gallstone colic. The patient had lost fifteen pounds in weight and was so reduced in strength that he could not work more than three days in the week. He had been treated for "ague," "indigestion," "acid dyspepsia" and "pulmonary tuberculosis." In my examination, however, the tuberculin test was negative, while Cammidge's pancreatic reaction was positive. A diagnosis of gallstones with subsequent pancreatitis was warranted.

It scarcely seems proper to speak of symptoms existing for a period of from two to six years as "inaugural symptoms," yet it has been my experience that these mild symptoms do persist for that length of time. In every instance, too, operation has disclosed either the presence of gallstones, the indubitable evidences of their presence in the immediate past, or the presence of marked inflammation in the gall tract. In every instance, also, drainage of that tract has resulted in the abolishment of symptoms.

While exploration, based on these inaugural symptoms of Moynihan, may occasionally lead us into an operation for cholecystitis without gallstones, this certainly need be no cause for regret. The cholecystitis of itself demands relief. The previous continual suffering of the patient, the associated incapacity for continuous and productive labor, and the subsequent postoperative relief, justify the operation. The fact that inflammatory disease of the gall tract, especially of the gall bladder, is so frequently but a precursory event in gallstone formation, still further justifies the measure, if further justification is necessary.

Taken in connection with these inaugural symptoms, however slight they may be, a history of a preceding attack of typhoid fever is strongly confirmatory of the presence of gallstones. In all such cases the Widal reaction should be undertaken and the urine and feces examined for typhoid bacilli. Positive findings will mark the patient as a typhoid-carrier and exploration will almost invariably disclose the presence of gallstones.

The one great stumbling-block in the way of an early diagnosis of gallstone disease is the allurements of jaundice, which seems to have bewitched the judgment of so many medical men, in that they demand its evidence before admitting the presence of gallstones. Jaundice, however, is an infrequent and inconstant event in gallstone disease and, when present, is as a terminal, rather than as an inaugural one. Too frequently, indeed, does jaundice announce the advanced stage of a secondary chronic pancreatitis. It is high time that the medical profession should break away from the fetish of jaundice; that it should recognize the presence of gallstones by their inaugural symptoms; that it should appreciate the gravity of gallstone complications and sequels, and that it should forestall such complications and sequels by the institution of operative procedures immediately following the establishment of a diagnosis.

234 Michigan Street.

Angioneurotic Edema.—S. Seilikovitch, in the *Archives of Pediatrics*, May, states that in his opinion the condition known as periodic, recurrent or cyclical vomiting, often at first mistaken for acute indigestion or obstruction of the bowels, may be diagnosed by exclusion as angioneurotic edema of the stomach. The same holds good in regard to the condition known as "hydrops articulorum intermittens," described by some authors as a distinct disease. Seilikovitch believes that it is simply angioneurotic edema of the joints.

events, but to the mild symptoms of concurrent cholecystitis and cholelithiasis.

A due appreciation of the diagnostic value and accuracy of the inaugural symptoms of gallstone disease, nearly all of which are referred by the patient to the stomach, will result, not only in a most decided and striking diminution in the number of diagnoses of "indigestion," of "dyspepsia" and of "biliousness," but also in a confirmation, by operative exploration, of the accuracy of postmortem findings as to the frequency of gallstone disease.

A few surgeons, operating largely in the pelvis and lower abdomen, have been making, in a desultory way, "touch" examinations of the gall bladder through a low abdominal incision. Failing to determine the presence of gallstones by this long-distance finger-tip touch of the globe of the gall bladder, they have gone on record as questioning the accuracy of postmortem findings as to the relative frequency of gallstones. Small calculi, even in considerable number, lying in a full gall bladder, easily may be overlooked by such palpation, while the exploration of the ducts, difficult at times through a high incision, is, in the great majority of instances, an impossibility through a low incision. Conclusions based on such incomplete attempts at examination are positively void of value.

Until, by either a large number of postmortem observations or an extensive series of complete and pains-taking examinations of the bile tract in the living, we are able to controvert the findings of Riedel, Kehr, Recklinghausen and others in Germany, of Voelcker, Brockbank and Cooper in England, and of Mosher and Herter in America, we must accept the statements that from 6 to 10 per cent. of adults in these countries are the subjects of gallstone disease.

During a recent six weeks spent with Mr. B. G. A. Moynihan at the Leeds General Infirmary, I was deeply impressed by the ease and certainty with which he diagnosed the presence of gallstones at a much earlier period than is possible if one is to be guided alone by the symptoms so usually attributable to such disease, and so uniformly emphasized in our text-books and special articles on the subject. By an extensive and critical study of the "pathology of the living" as observed on the operating table, rather than by an unquestioning acceptance and reiteration of the old teachings in pathology, Moynihan has been able to define certain early or inaugural symptoms which precede by a considerable period the common and apparent phenomena so generally held as indicative of gallstone disease, but which we must now recognize as the symptoms of terminal events.

In an address on "Inaugural Symptoms"² and in a paper entitled "Cholelithiasis: Its Early Recognition and Early Surgical Treatment,"³ Moynihan has clearly stated these early symptoms and the underlying conditions for which they stand.

These inaugural symptoms are slight in their intensity, and when considered individually would, with but one or two exceptions, scarcely ever point to the bile tract as the seat of disease. Collectively, even, were it not for the observations made by Moynihan on the living, enabling us to interpret aright their significance, they would be considered, almost invariably, as indications of gastric disease.

In a rapidly growing series of cases in which I have

operated, basing the necessity for the operation on these inaugural symptoms, gastric disease has been found in but one case. In that case, Cammidge's pancreatic reaction being positive, no gallstones were found, but a chronic cholecystitis with pericholecystic adhesions was present, as was a chronic pancreatitis and a prepyloric gastric ulcer.

Of the inaugural symptoms, pain, while present, is not marked, being rather a discomfort, an uneasiness, a flatulence, an ill-defined sensation of tightness, weight and oppression, always referred to the stomach, coming on in from half an hour to three-quarters of an hour after meals and being relieved by belching or vomiting, although vomiting is a rather infrequent event. In two cases in which I recently operated, vomiting, generally occurring before the meal was completed, was a frequent and conspicuous event. In one, the vomiting was preceded, momentarily, by severe pain referred to the stomach. In the other, severe pain was never present; but a feeling of discomfort, of oppression, of shortness of breath, first manifest early in the course of the meal, steadily increased in severity as the meal progressed, until suddenly, preceded by an instant of nausea, vomiting occurred. The one great complaint of this patient was an increasing shortness of breath as the meal progressed. One patient, a boy of 6 years, relieved of his pain by vomiting and having his hunger unappeased, would return to the table and eat again, only to have a repetition of the pain and vomiting. Several of my patients presenting the above-mentioned symptoms, complained also of a sense of discomfort and uneasiness along the free border of the right lobe of the liver, yet this discomfort never approached the dignity of a pain.

If this inaugural pain is at times somewhat more severe than at others, it may radiate from the stomach through to the right shoulder. With the pain, be it ever so slight, frequently comes a feeling of cold, a shiver, a chilliness, never severe, never of long duration, occurring after meals and more often noticed in the evening than at any other time. One of the patients above referred to volunteered the statement: "I so often feel chilly in the evening."

Moynihan justly attaches considerable importance to a catch in the breath as an inaugural symptom of gallstone disease, and I can not refrain from quoting him as follows:

In such attacks there may be "a catch in the breath"; the patient says that it is impossible for a deep breath to be taken, for, as the chest fills, a sudden stabbing pain is felt which cuts short the inspiratory effort. This spasm of the diaphragm is very characteristic of gall bladder diseases, and often distinguishes them from gastric and duodenal conditions, with which they are apt to be confounded.

Drowsiness, inability to concentrate the mind, "a sensation of weight and fulness in the head, . . . migraine are sometimes noted, especially when the patient is fatigued." Dr. Leonard Molloy, quoted by Moynihan, calls these symptoms "gall-bladder dyspepsia."

While tenderness on deep inspiration, from thumb pressure under the edge of the ribs and against the gall bladder, is present in the later stages of gallstone disease, it is also present in association with the inaugural symptoms and is a most important confirmatory sign of cholecystitis. All of my early cases in which it has been present to a marked extent have shown a decided degree of cholecystitis and, in several cases, cholecystitis without gallstones was found on operation. In one of these latter cases at least two-thirds of the gall bladder wall retained its natural suppleness and its bluish color;

3. Practitioner, December, 1908.

Considering the appalling array of drugs that have been offered for the treatment of pertussis, one hesitates to make any assertions. This, however, is no new drug, but one of recognized utility, only presented in a form that is new, and that will the better bring its virtues to bear on the site of the disease.

I am quite convinced of its value. To cite one illustration: In a family of three children, I gave it to the two older and, observing a little resistance on the part of the baby, not quite 2 years old, I treated it with other drugs. The two older, whose cases were severe at the beginning, immediately began to improve. The baby grew worse. The mother, convinced of the benefits derived, then used it of her own accord on the baby. In a few days she succeeded in getting it to take the vapor in a satisfactory manner, and it also showed immediate improvement. The chief difficulty I have met is that, after the first week, the child is so much better that the mother neglects to use the medicine systematically.

In a brief way, I wish to mention some other of these modified petrox preparations which I have had made and which, I believe, possess virtue sufficient to warrant their addition to our armamentarium. Incidentally I might mention that in the iodine preparations of liquid petrox, the ammonia is rather of advantage, considering the uses of the preparation.

Benzoin compound is a preparation that I have used in this potassium petrox solution and have found very soothing in acute inflammations of the respiratory mucous membrane.

Guaiac is of accepted value in certain forms of tonsillitis and, dissolved in the potassium petrox solution, can be used more frequently than the alcoholic tincture.

Lately, carrying out the suggestion of Dr. B. Alexander Randall, of using dionin for its absorptive effect on cicatricial tissue, I have had made a 3 per cent. solution of dionin. Filling the Politzer bag with this vapor from the nebulizer, I have forced it into the middle ear through the Eustachian catheter. Where there is sclerosis and an old dry perforation, the nebulizer can be directed into the meatus. The value of this drug has hardly had time to be demonstrated, but this method of administration appeals to me as more thoroughly distributive of the drug than as commonly used.

Other resinous and alkaloidal drugs can doubtless be used in the same manner if desired. In closing I wish to express my appreciation of the experimental work and pharmaceutical skill of Mr. W. G. Nebig, which contributed materially to the degree of success so far obtained.

SCARF-PIN SWALLOWED BY INFANT

CLARENCE C. PARKS, M.D., LEECHBURG, PA.

A case report in *THE JOURNAL*, April 10, 1909, p. 1180, of a darning-needle extracted from the epigastrium of an infant, brings to my mind a similar case.

Baby A., 9 months old, breast-fed and in every way a healthy child, had in some manner obtained his father's stick-pin from his tie and swallowed it. The father did not miss the pin until ready to go to bed and then supposed he had left it at the barber-shop. The next day, while the mother was changing the baby's napkin, she noticed something protruding from the anus, and on closer inspection discovered it to be the stick-pin with the large part or head of the pin protruding. The pin measured $2\frac{1}{2}$ inches.

CERVICAL DISLOCATION

FRANK M. SHERMAN, M.D.

WEST NEWTON, MASS.

I reported two cases of dislocation of the neck in the *Boston Medical and Surgical Journal*, April 25, 1907. Since that date three additional cases have been seen—one a slight subluxation that was self-reduced during the relaxation of sleep; the other two the cases reported below.

Besides these cases may be mentioned one seen¹ in 1903. This makes a total of six cases in the past five years, five of them during the last two years.

These cases occurred in the practice of four different physicians. This experience tends to establish the probability that the condition is not a rare one, and that its apparent rarity may be due to lack of recognition.

It appears to be true with respect to some diseases that as they have become well understood they have apparently increased in frequency. Appendicitis may be mentioned as an example. Another instance is the disease actinomycosis, of which Dr. Maurice H. Richardson says:²

"Since Dr. C. A. Porter first called attention to the frequency of actinomycosis in the jaw cases at the Massachusetts General Hospital, the number of instances of this disease appearing in different parts of the body was apparently multiplied a hundredfold."

Is it not possible that dislocations of the neck, particularly subluxations, also occur oftener than is supposed? And that the cases which are thought to be torticollis or stiff neck from "cold" are in reality of this nature? Such, at any rate, is my present opinion. I would, therefore, urge careful attention to the points of differential diagnosis, and especially the application of the appropriate movements of reduction in all cases of suddenly acquired stiff neck.

If the articular process on one side has become displaced forward, the head will be more or less tilted toward the opposite side; it may also be rotated toward the opposite side. This is the position in subluxation. If the unilateral dislocation is complete, so that the articulating process has gone far enough to drop down in front of its fellow articulating process, the head will be turned toward the opposite side, but tilted toward the same side as the lesion.

The method of reducing these dislocations, worked out by G. L. Walton, is to make dorsolateral extension and then rotation to place, usually under complete anesthesia; but I have succeeded in one case in reducing the displacement without anesthesia. This treatment is of the greatest satisfaction to the surgeon and of benefit to the patient.

The following cases are of interest, both having occurred during sleep from a sudden twisting movement:

Fifth Case.—A young woman, aged about 19, awoke suddenly in much pain and unable to turn her head. This condition continued during the remainder of the night and the following day, when I was asked to see her and relieve her "stiff neck." The head was tilted to the left and slightly turned to the left; the muscles on the right side of the neck were tense. On the following morning the condition remained much the same. Examination revealed the spinous process of the fourth (?) cervical vertebra about one-half inch out of line with the others. Under ether anesthesia the head was bent diagonally backward and to the left and then rotated to place. At once the condition of the neck was changed from that of rigid stiffness to one of free mobility. On recovery from the anesthetic

Clinical Notes**ANKYLOSTOMA DUODENALE**
(*UNCINARIA AMERICANA*) *JOSEPH LEIDY, JR., M.D.
PHILADELPHIA

Some years ago (1904) the Smithsonian Institution published the collected "Researches in Helminthology and Parasitology," written by the late Prof. Joseph Leidy.¹ The publication consisted of the collected essays and original investigations² from 1844 to 1891. Unusual care was observed that the work should be complete in all details, but, as frequently occurs, owing to the vast amount of scientific literature which now burdens the transactions of our various learned societies, the title of one paper was not catalogued, and the communication was lost to the specialist interested in similar lines of investigation. The brief observations were presented under the title, "Remarks on Parasites and Scorpions, May 5, 1886."

Leidy described three specimens of worms obtained from an anemic cat, presumed to be specimens of *Ankylostoma duodenale*, which were sent to him by Dr. Belfield, of Chicago, for determination. He remarked:

On superficial examination I supposed the worms might belong to *Strongylus tubiformis*, a closely related parasite infesting the cat. The specimens, however, exhibit the same structure of the mouth as is described in the *Ankylostoma duodenale* of man. . . . [description follows].

The finding of this parasite in the cat in this country renders it probable that it may also infest man with us, and is probably one of the previously unrecognized causes of pernicious anemia.

The occurrence of the same parasite in the cat is also of interest, as heretofore it has only been noticed in man.

In reply to the question of Dr. Weir Mitchell as to how the animal gained entrance to the system, Leidy stated:

It is supposed that ankylostoma gain entrance to man through the drinking-water; and if that is the case the cats probably obtain it in the same way. If cats in this country obtain it from the drinking-water it is probable that with us man may do so.

It is curious that it should be found in the cat; generally we find that similar parasitic worms are found only in animals closely related to one another.

So far as we know, the *Ascaris vermicularis* occurs in no other animal than races of men. The cat has its own ascaris and this is found in various species of cats all over the world. There is another found in the dog, which is also found in the wolf. Again, the ordinary tapeworm of the dog is found in all sorts of dogs. I have a specimen from the wolf in the west, and I have another which Dr. Kane obtained from an Esquimaux dog in the north; as I have said, worms of the same species in the same stage usually only infest animals which are closely related.

The original communication was made to the College of Physicians of Philadelphia and was followed by further observations on *Trichina spiralis* and scorpions from Mexico. The date, May 5, 1886, is of historic interest.

1319 Locust Street.

QUININ INHALATIONS IN PERTUSSISWITH A CONSIDERATION OF OTHER PETROX
MEDICAMENTS *H. C. MASLAND, A.M., M.D.
PHILADELPHIA

The physician has possibly no more irritating sense of helplessness than when called to treat a patient with whooping cough. Besought from day to day by a distressed mother for a greater measure of relief, he tries one and another drug, only to realize the inadequacy of them all.

A perusal of the literature demonstrates that quinin, despite all the newer drugs, holds its own. More than a year ago, in looking over some literature on the subject, the proposition to bring quinin for its germicidal effect into immediate contact with the respiratory mucous membrane, attracted my attention.

Michael, forty years ago, recommended the insufflation of quinin and benzoin powder into the nostrils. Litzerich mentions in Ziemssen's Encyclopedia that he tried an inhalation of a solution of sulphate of quinin in one case, but that the child was removed from the hospital too soon for any conclusions to be drawn.

At the present time quinin is usually given internally; when given locally it is in the form of a powder combined with minor drugs, and insufflated into the nostrils. The insufflated powder can reach only the prelaryngeal areas. To me, believing as I do that the infecting germ has its habitat throughout the respiratory mucous membrane, the idea of bringing the drug in contact with the whole tract seemed promising. The frequent use of an acid solution of quinin sulphate, by inhalation as suggested by Litzerich, would be sufficiently contraindicated because of its injurious effect on the teeth. To accomplish this purpose, I experimented with the liquid petrox of the National Formulary. Finding that the ammonia of this preparation caused some irritation of the nasal mucous membrane, I substituted therefor potassium. Using a corresponding portion of potassium hydrate makes a thick solution, requiring warming to liquefy. After considerable experimenting, a solution in which the potassium was considerably lessened in amount was found the most satisfactory.

The following is the stock formula¹ as given me by Mr. W. G. Nebig:

R.	gm. or c.c.	
Potassium hydrate	29.6	℥.58
Alcohol, q. s. ad.	200	℥.5iss
Of this add:	5	℥.5iss
To		
Oleic acid	10	℥.33
Liquid petrolatum	25	℥.5iss

One ounce of this preparation will readily dissolve 30 grains of the alkaloid quinin. I have directed this to be used in a nebulizer not less than three times daily, preferably oftener. With very young children a mask or canopy over the head may be necessary. Older children will readily take, even ask for it, nebulized directly into the nostrils. In my experience, I have had no trouble in gaining the confidence of the child and being able to give it a concentrated inhalation of the drug.

* Read before the Northwest Medical Society, May 3, 1909.

1. Some preparations are made by dissolving the drug in the alcoholic solution of potash, some, as quinin, in the finished solution. No more alcohol than the amount stated should be used.

* Read before the Pathological Society of Philadelphia, May 13, 1909.

New and Nonofficial Remedies

SINCE THE PUBLICATION OF THE BOOK "NEW AND NONOFFICIAL REMEDIES, 1909," THE FOLLOWING ARTICLES HAVE BEEN ACCEPTED BY THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION. THEIR ACCEPTANCE HAS BEEN BASED LARGELY ON EVIDENCE SUPPLIED BY THE MANUFACTURER OR HIS AGENT AND IN PART ON INVESTIGATION MADE BY OR UNDER THE DIRECTION OF THE COUNCIL. CRITICISMS AND CORRECTIONS TO AID IN THE REVISION OF THE MATTER BEFORE PUBLICATION IN THE BOOK ARE ASKED FOR.

THE COUNCIL DESIRES PHYSICIANS TO UNDERSTAND THAT THE ACCEPTANCE OF AN ARTICLE DOES NOT NECESSARILY MEAN A RECOMMENDATION, BUT THAT SO FAR AS KNOWN IT COMPLIES WITH THE RULES ADOPTED BY THE COUNCIL.

W. A. PUCKNER, SECRETARY.

(Continued from page 1499)

MERCURIC CYANIDE—Hydrargyri Cyanidum.—Hydrargyrum cyanatum (Pharm. Française, edit. 1908).

Mercuric cyanide, $\text{Hg}(\text{CN})_2$, is the mercuric salt of hydrocyanic acid.

Prussian blue and mercuric oxide in water are boiled until the mixture is brown; the mixture is filtered, acidified with hydrocyanic acid, evaporated and allowed to crystallize in a cool place. It is also prepared by the action of hydrocyanic acid on mercuric chloride. Colorless or white, prismatic crystals, odorless, and having a bitter, metallic taste (the salt is exceedingly poisonous). It is darkened on exposure to light. Soluble at 15°C . (59°F .) in 12.8 parts of water, and in 15 parts of alcohol; in 3 parts of boiling water, and in 6 parts of boiling alcohol; very sparingly soluble in ether.

When slowly heated in a glass tube, the salt decrepitates, and decomposes into metallic mercury and inflammable cyanogen gas, which burns with a purple flame. On further heating, the blackish residue, consisting of para-cyanogen with globules of metallic mercury, is wholly dissipated.

If 1 part of the salt be gently heated with 1 part of iodine in a dry test-tube, it will produce at first a yellow sublimate which afterwards becomes red, and above this a sublimate of colorless, needle-shaped crystals.

On adding hydrochloric acid to the aqueous solution of the salt, the odor of hydrocyanic acid is evolved.

A 5 per cent. aqueous solution of the salt should be neutral to litmus paper, and should not yield, on the gradual addition of a few drops of potassium iodide test solution, either a red or a reddish precipitate, soluble in an excess of the precipitant, nor should it yield a white precipitate with silver nitrate test solution (absence of mercuric chloride).

If mercuric cyanide be dissolved in an aqueous solution of sodium chloride the addition of phenolphthalein to this solution should produce no red coloration (absence of mercuric oxide).

Ammonia should not color an aqueous solution blue (absence of copper), nor should a solution of copper give a brown color or precipitate (absence of potassium ferrocyanide). The presence of large quantities of potassium sulphate may be demonstrated by lighting, leaching the ash and testing the filtrate with barium. Dilute sulphuric acid should not liberate hydrocyanic acid (absence of potassium cyanide). Ammonia should dissolve mercuric cyanide without producing a white precipitate (absence of oxycyanide). (Pharm. Française, edit. 1908.)

Action and Uses.—Mercuric Cyanide has been reported to be as actively antiseptic as mercuric chloride and to be less irritating; but this has been questioned. It is used locally and internally like mercuric chloride.

Dosage.—Internally from 0.004 to 0.008 Gm. (1/16 to 1/8 grain); locally, solutions of 1-4000 to 1-2000 may be used for applications to the eye or other mucous membrane; 25 to 35 minims of a 1 per cent. solution may be used hypodermically without causing local irritation. Death has occurred from the use of a vaginal injection containing 0.9 Gm. (14 grains) of mercuric cyanide.

In diphtheria and croup it is used in 0.01 per cent. solution and as a gargle or internally in doses of 0.0005 Gm.-0.001 (0.0077-0.0154 grain). In rhinitis fibrinosa it is used on a tampon in 0.04 per cent. solution.

KEFIR FUNGI.—A mixture of bacteria and yeasts capable of causing lactic acid fermentation of milk.

Kefir occurs in the form of white irregular roundish bodies, size of a walnut, with a very rough, furrowed surface, and a tough gelatinous consistency. The substance contains *Saccharomyces cerevisiae* (Heyden), *Bacillus acidilactici* (Pasteur), *Dispora Caucasica* (Kern). It acts on milk as follows: Fat, salt and water of the milk remain unaffected. The lactose is gradually decreased and the lactic acid increased. Alcohol is produced along with carbon dioxide. 10 per cent. of the casein is converted into acid albumin and peptones. 10 per cent. into hemialbumose and the rest loses its lime. (U. S. Disp., 19th ed., p. 1540.)

Action and Uses.—Kefir fungi are used for the preparation of fermented milk which contains lactic acid, alcohol, the fats, salt and water of the milk. Kefir milk acts as an easily digestible food in dyspepsia and lack of digestive power. It is

also serviceable in the prevention of intestinal putrefaction.

Dosage.—Kefir kumyss may be prepared by adding active kefir grains to fresh cows' milk, kept at a temperature of 21° - 27°C . (70° to 80°F .) until the effect of fermentation becomes apparent by the rising of the grains to the surface. The grains may then be strained off, and the milk, which now contains sufficient yeast-cells to insure continuance of the fermentation, left to itself in well-corked bottles.

TRANSFER OF AGENCY.

Stovaine (see New and Nonofficial Remedies, 1909, p. 123). Formerly sold by Walter F. Sykes, New York, is now sold by the Parmele Pharmaceutical Co.

ARTICLES DROPPED FROM N. N. R.

Salit (Heyden Chemical Works). The Council, having been informed that this product is advertised in the daily papers in Germany, reconsidered its acceptance and decided to omit it from New and Nonofficial Remedies (see Pharmacology Department, this issue).

Migrainin (Victor Koechl & Co., New York). The Council voted to rescind the acceptance of Migrainin for non-compliance with rules 1 and 6 and to omit the article from New and Nonofficial Remedies (see Pharmacology Department, this issue).
(To be continued.)

Therapeutics

ACUTE ARTICULAR RHEUMATISM

In the *New York Medical Journal*, August 29, and Sept. 5, 12, and 19, 1908, appears a series of articles on the treatment of this disease. Twelve physicians contribute articles in the discussion of this subject.

For the purpose of analyzing the treatment and arriving at a conclusion of the best management of this disease, it seems best to divide the treatment under three heads; general, local, and specific.

GENERAL TREATMENT

The patient, of course, should be in bed, and it is emphasized that he should remain there several days after the temperature has become normal. Five of the writers insist that the patient lie between blankets; two make this optional; and the remainder allow it to be implied that the patient lies between sheets.

The majority order early purgation, and also give calomel, mostly followed by a saline, and one specifies magnesium citrate. One physician gives calomel in divided doses until purgation, which we do not consider good treatment. Daily movements are advised, with sodium phosphate by one contributor, and Rochelle salts by another, and others say "avoid constipation," or "cause daily movements," without stating how they accomplish this. One prefers to use an aromatic fluid-extract of cascara sagrada (*rhamnus purshiana*); another uses an aloin, belladonna, ipecac and strychnin tablet. In other words, it seems generally, as is true in the treatment of all infections and all feverish processes, that a daily movement of the bowels should be caused in the pleasantest manner possible with the least possible pain, and without causing diarrhea; calomel or castor oil as a primary purgative, and whether small doses of a saline, or other gentle laxative, should be used, daily, is a matter of individual choice.

All the authors allow plenty of plain water or mineral water, barley water, or oatmeal water. In other words, plenty of water in a disease that causes so much perspiration and requires so much elimination is desirable and advisable. Lemonade with but little sugar is advised by some, and certainly lemons or oranges may be allowed in rheumatism, even by those who believe that

there was noted a marked change in the condition and sensations of the patient. Before the manipulation there was stiffness and pain, afterward complete relief from these symptoms. Deep tenderness in the right side of the neck remained, however, and persisted for several weeks.

Sixth Case.—A young man had had a minor degree of the same trouble twice before during the last six months, with recovery. On awakening, Jan. 24, 1909, he felt pain and stiffness in the left side of the neck. It grew worse during the day. The head was tipped decidedly to the right; the muscles on the left side were tense; the left side of the neck was painful and tender. The diagnosis was subluxation of articular process on the left. Bearing in mind the history of previous attacks which were thought to be of the same nature, and that these slight displacements had been self-reduced, I attempted to correct the subluxation without ether; this was found somewhat difficult on account of the spasm of the muscles, but it was accomplished successfully with immediate relief. A stiff collar was applied. Some tenderness persisted for a few days. The collar was worn at night for some time.

CONCLUSIONS

Many cases, perhaps all cases, of suddenly acquired stiff neck, with distortion, or abnormal position of the head, which position the patient is unable to correct because of the pain produced, are cases of more or less pronounced dislocation of the articular processes of the vertebrae.

In the great majority of these cases the articulating surfaces are but slightly displaced, so slightly that many of the dislocations have been self-reduced during sleep or during the relaxation of anesthesia.

These cases may occur during sleep or from direct trauma, as in football, and particularly from sudden turning of the head, especially if the muscles of one side are tense, as when carrying a heavy weight in one hand.

Treatment by laterodorsal extension and rotation is very satisfactory and the extreme cases are probably as amenable as the lighter ones to this treatment.

NEW TONSIL-SEIZING FORCEPS

E. E. CLARK, M.D.

DANVILLE, ILL.

All forceps are intended to grasp the tonsil parallel with its long diameter, a procedure which is often difficult. The forceps here described are intended to grasp

Forceps for grasping the tonsil across its short diameter.

the tonsil across the short diameter, which is always easy. The grasping blades are so shaped and toothed that they take a firm hold and do not tear out. When the jaws are opened to the fullest extent they occupy no more space in the fauces than when opened just a little, which is in marked contrast to other forms of forceps.

When the jaws are closed they lock firmly. If one suddenly desires to remove the forceps, the little button near the two rings is touched, and the coiled spring instantly throws open the jaws. If one desires to use the tonsillotome he can pass the forceps through the ring before grasping the tonsil.

MYOSPASM IN WHICH ONE LEG EXHIBITS TONIC, THE OTHER CLONIC, FORM

FRANCIS W. WHITE, M.D.

Demonstrator of Clinical Medicine, Jefferson Medical College
PHILADELPHIA

The following history is given somewhat in detail, which, on account of the oddity of the condition, is permissible:

Family History.—This, though very carefully elicited, shows nothing very interesting. Paternal grandfather, maternal grandmother and aunt suffered from articular rheumatism, the second succumbing to cardiac complications. The brothers and sister are strong and healthy.

Personal History.—The patient is 8 years old, pale, of ordinary muscular development and mentality. At twelve months of age he suffered from cholera infantum, and at five years from whooping cough, followed by measles; he has been otherwise fairly healthy and active until the onset of present condition.

Present Illness.—About eight months ago a mosquito-bite on the left foot, becoming highly irritated, caused the patient to limp on that side, also to turn the toes in on the same side. The limp continued about one month and gradually disappeared with subsidence of the inflammatory condition, but the inversion of the toes has persisted. Shortly after this the child fell and bruised his right knee. This caused him to limp on this side, also to invert the toes of the right foot and to keep the right knee joint perfectly rigid. The local injury was of slight degree, as the signs quickly disappeared. Although of over six months' duration the peculiar gait has not been absent for any appreciable length of time. Since the child has been under observation he has been highly nervous, and while on a sedative treatment the local conditions apparently improved, but it was only temporary, as a strict isolation could not be carried out. Wishing to eliminate any undiscovered orthopedic condition I referred the case to Dr. C. H. Muschlitz, whose findings are negative. Later Dr. G. E. Price made an exhaustive neurologic examination.

Examination.—At present the patient is quite irritable and during examinations is extremely nervous. His station is very uncertain but does not display the Romberg sign. When asked to walk he starts off suddenly, the toes of both feet are inverted, and there is marked rotation on the right os calcis. The right knee joint is rigid when the corresponding foot is brought forward, but when the superincumbent weight of the body is brought to bear on it there is an outward and forward rotation, which, with the position of the feet, produce a most extraordinary and awkward gait. This can be completely corrected for a short time by making the patient count rapidly while walking. If the patient is placed in the recumbent position, the maneuver of flexing the thigh on the abdomen and the leg on the thigh can be accomplished only with difficulty and maintained for but a very short time. The reverse procedure is attended with the same awkward movement as in walking. The left leg does not show the spastic condition or tonic contraction of the other, it being flaccid with at times an irregularly recurring spasm which is slower and more persistent than a choreiform movement, and more coordinate than an athetoid movement. There is no muscular wasting, the legs being about the same size. Both ankle clonus and Babinski's sign are absent and the knee-jerk can not be obtained on account of the spasm. The upper extremities are normal, the grip being equal in both hands and the spasm or twitching are absent. The reflexes are about normal. There are no abnormal conditions to be found in the face and the special senses are not affected. Hysterical stigmata are absent.

Vaginitis.—Paul Loze, in the *American Journal of Urology*, states that in profuse suppuration of the tunica vaginalis the prognosis is generally serious, as there usually is inflammatory edema of the scrotum, high temperature and a serious general condition. Treatment consists in incision and free drainage.

sules are likely to cause gastric irritation. Sodium salicylate may be administered as follows:

R.	gm. or c.c.	
Sodii salicylatis	20	or 5v
Aque gaultheriæ	100	fl. 3iv

M. et Sig.: A teaspoonful, well diluted, every three hours, or as directed.

Or:

R.	gm. or c.c.	
Acidi salicyli	10	or
Sodii bicarbonatis siccat	10	aa. 3iiss

M. et fac. chartulas 20.

Sig.: One powder, dissolved in water, and drunk while effervescing, every three hours, or as directed.

As soon as the pain is less, the temperature less, the swelling of the joints less, and no new joints become affected, the sodium salicylate should be again diminished in amount and frequency. It should be stopped altogether as soon as the joint symptoms have disappeared, or at the end of a week or ten days. The prolonged use of salicylates is pernicious to the blood and circulation, and serious and protracted anemia and debility have followed its too long use in large doses. On the other hand, as recommended by some of the contributors of the above articles, the substitution, for the salicylate, of potassium acetate, bicarbonate, or citrate, in other words, an alkaline treatment for a series of days, and then again to give the salicylate seems to be very advisable. Potassium citrate is the pleasantest and acts as satisfactorily as either of the other potash salts. It may be given as:

R.	gm. or c.c.	
Potassii citratis	40	or 3x
Aque menthæ piperitæ	200	fl. 3vii

M. et Sig.: Two teaspoonfuls, in water, every three or four hours.

As soon as the urine becomes alkaline, the frequency of the administration of the alkali should be diminished.

In this disease that tends so frequently to recur, and to recur immediately, it is advisable to give two or three days of the salicylate treatment after a week of the alkaline treatment, and then again every two weeks for several times. It has even seemed advisable to give a child who has had rheumatism a week's treatment of salicylate of soda, in the proper dose for its age, every two or three months after recovery from its primary attack, and then once in six months for several years.

While heat, whether dry or moist, and especially the hot-air body treatment may preclude the necessity of using morphin for pain in this disease, more especially perhaps than in some others, pain can not be endured, and the patient should not be allowed to suffer. A disease that causes pain on every movement, voluntary or involuntary, of the body requires a narcotic, and morphin is often needed, and should be given hypodermatically, or by the mouth, depending on the intensity of the pain, or whether or not, it disturbs the stomach when administered by the mouth. It is rare that codein is strong enough, except in large doses, to stop arthritic pain, and there is really very little difference whether small doses of morphin are given or large doses of codein, as the effect produced is similar. If much morphin is administered so that the patient sleeps and is indifferent to his sensations, he must be aroused periodically and urged to evacuate his bladder.

Ordinarily, the coal-tar analgesics should not be used, as, in the first place, if the pain is severe they are not strong enough, and in the second place the salicylates are debilitating, and no other debilitating drug should be given. If there is high temperature in the early part

of the disease a few doses of acetphenetidinum (phenacetin) may be administered.

In the treatment of this disease, it should be urged that the heart be watched daily by stethoscopic examination, to note as soon as signs of endocarditis occur. This complication is so insidious that it may not cause symptoms appreciable to the patient. There may, however, be an increase of temperature, as there may be cardiac pain or distress. While it is not the object of this article to describe the treatment of endocarditis, it may be stated that an ice bag over the heart may inhibit the inflammation, that the salicylates should be stopped if endocarditis occurs, and that rest and convalescence after such a complication should be greatly prolonged.

Profuse sweating without fever requires frequent spongings with hot water, may require spongings with warm alcohol, and may even require a nightly dose of atropin, from 1/200 to 1/100 of a grain. If the heart has not been affected, ergot may be given for its aid in checking the profuse perspiration.

Certainly during convalescence, and often best after the first ten days or two weeks, iron should be administered. It should be remembered that the diet advised for rheumatism contains no iron, that the disease is debilitating to all the blood-making organs, that the salicylates and alkalies are both debilitants of the blood, and consequently iron is indicated. Many a prolonged anemia following rheumatism is due to the shortage of this needed element in the body. Iron may be administered in any simple manner, as by a 0.05 gram (or 1 grain) capsule of reduced iron three times a day, or by a saccharated oxide of iron (*Eisenzucker*) three grain tablet, three times a day, or as follows:

R.	gm. or c.c.	
Tincture ferri chloridi	25	or fl. 3i

Sig.: Five drops in a small glass of fresh lemonade, three times a day, after meals.

Circulatory weakness during rheumatic fever may be combated with strychnin, with camphor, with aromatic spirits of ammonia, rarely with alcohol, sometimes with caffein, and exceptionally with strophanthus or digitalis, the latter provided that there has not been prolonged high fever and there is no acute endocarditis present.

Lees, in the *British Medical Journal*, Jan. 16, 1909, says that part of the lack of successful treatment of rheumatism with salicylic acid is due to the belief that it is a heart depressant. He insists that it is not detrimental to the heart, and that all unpleasant "side effects" may be prevented by giving sodium bicarbonate coincidentally in twice the amount of the salicylate. The initial adult dose is 15 grains, given ten times the first twenty-four hours, or 150 grains for the first day. He would then increase each dose for the second day by at least two grains, viz., 20 grains more than the first day, and would again increase the third day, such increase continuing until the temperature is and remains normal. With each dose of salicylate, however, he would give twice as much bicarbonate of sodium. He believes the cause of the cardiac complication is due to the acids of the toxins of the disease, and that the way to combat this is by alkaline salt, because potash is slightly depressing to the heart, and soda almost not at all.

His initial dose for a child from seven to twelve years of age is 10 grains, and ten doses a day, or 100 grains the first day, and then increased as above.

When the symptoms are all ameliorated, Lees then gradually reduces the twenty-four hour dose of salicylate.

SATURDAY, JUNE 5, 1909

THE CLINICAL ANALYSIS OF GENERAL SENSATION

From the careful analysis of the nervous symptoms in a very large number of cases of visceral disease and of lesions of the peripheral nerves and spinal cord, a group of English neurologists has recently made important additions to our knowledge of the cutaneous sensations, their peripheral nerves and central conduction paths.¹

It appears that the afferent nerves of general sensation are very much more complex than has hitherto been supposed. We may consider these pathways in three sections: (1) the peripheral division, carrying the impulses to the surface of the spinal cord; (2) the intraspinal division, and (3) the cerebral division. The limits of the peripheral division do not coincide with those of the peripheral neurone. The justification for this treatment lies in the observed character of the sensory disturbances in the central and peripheral courses of the path, peripheral lesions producing a wholly different type of symptom-complex than central. The explanation for this is to be sought in the phylogeny; the spinal roots being the most conservative part of the path, functional adaptations developed in the course of the phylogeny have taken different directions centrally and peripherally from this fixed point. Observation shows that the root fibers of the segmental spinal nerves and their associated secondary paths are so rearranged within the spinal cord as to bring together fibers conducting the same kinds of impulses from different segments into functionally homogeneous tracts.

In general sensation (exclusive of visceral sensations), Head distinguishes three types of sensibility. These are confused in the spinal roots, but may be separated in the peripheral nervous system, so that a peripheral lesion may affect one and not the others. These systems are:

1. Deep sensibility. This system is preserved after destruction of all afferent cutaneous fibers. Pressure can still be recognized and discriminated. Pain can be felt on application of a measurable pressure and the point of application of the pressure can be localized. Movements of the muscles can be recognized and also passive movements of the joints.

2. Protopathic sensibility. This is essentially punctate sensibility. The sense organs seem to be arranged in definite spots (for heat, cold or pain), but the sensations have no clear local sign. They may be recognized diffusely or else clearly referred to points remote from the spot stimulated, but rarely to the point of stimulation. This is subjectively general diffuse sensibility of a primitive phyletic type. Hair bulbs are innervated from this system. Its loss abolishes cutaneous pain, especially pricking, burning or freezing; sensations of heat from temperatures above 45 degrees C.; sensations of cold from temperatures below 20 degrees C.

3. Epicritic sensibility. Here belong light touch, especially on hairless parts, cutaneous localization, discrimination of compass points and discrimination of intermediate degrees of temperature ("warm" and "cool"). This system appears to be of later phylogenetic origin than the others. In regeneration of nerves it appears long after protopathic sensibility of the same areas of skin.

Painful stimuli may reach the spinal cord either through the peripheral protopathic or the deep peripheral system, and analgesia produced by peripheral lesions is always associated with the loss of the tactile elements of the corresponding sensation complex in the analgesic area. Superficial pain may be lost without loss of deep pain, but never without disturbance of superficial protopathic touch and temperature sensations. But when pain in a region is abolished by a lesion within the spinal cord, all pain (both deep and superficial) may be lost, with no disturbance of either deep or cutaneous tactile sensation. This shows that the protopathic and deep peripheral systems have lost their individuality as such on entrance into the spinal cord, the pain elements of each having been separated from the tactile and related to a common pain tract in the spinal cord.

The spinal redistribution of temperature nerves is even more striking. Destruction of either epicritic or protopathic fibers peripherally disturbs both heat and cold. If epicritic sensibility is abolished, the patient can not discriminate intermediate temperatures, but is sensitive to extremes. If the protopathic also is abolished, even extreme temperatures are lost. If either heat or cold is disturbed in these cases, the other is affected also. But a spinal lesion may abolish either heat or cold separately, and will abolish both intermediate and extreme degrees of sensibility, and that, too, perhaps with no disturbance of any form of tactile sen-

Sherren: Injuries of Nerves. New York, 1908, William Wood & Co.

sibility—a condition which could not arise from any form of peripheral lesion. All nerves for heat or cold reach a single spinal path, regardless of the path by which they enter the spinal cord.

The tactile functions are centralized in a similar way in the cord. Light (epicritic) touch is frequently dissociated from protopathic touch and pressure by peripheral lesions; never by central lesions. If tactile sensibility is lost at all in the latter case, all forms disappear from the area affected. Again, passive position and movement are always associated with deep sensibility in general in the peripheral nerves; but in the spinal cord they may be dissociated from all other forms of deep sensibility. In the epicritic peripheral system the discrimination of two points (compass test) is always associated with sensitiveness to light touch; but in the spinal cord these may be dissociated. All forms of tactile sensibility may be perfect in the case of a spinal lesion, and yet the discrimination in question be totally lost. This function has a certain physiologic independence, and these cases show that it has also an anatomic separateness.

The clinical study of the deep, protopathic and epicritic sensations is a matter of great difficulty, because of the rarity of uncomplicated lesions adapted to elucidate their relations and because few patients are either sufficiently well trained in introspection to give an accurate account of their sensations or able to devote the time necessary for their study. Accordingly, Dr. Head submitted himself to a carefully planned nerve lesion in order to be able to study the subjective phenomena at first hand in detail.²

In April, 1903, the radial and external cutaneous nerves of Head's arm were divided and during the succeeding five years the phenomena of restoration of function were very carefully studied by Head and Rivers. Immediately after the operation, though the skin supplied by the divided nerves was totally anesthetic, deep sensibility, as defined above, was found unimpaired under the same region. After about 50 days protopathic sensibility began to return, and for nearly a year thereafter the affected area showed deep and protopathic sensibility only, after which time epicritic sensibility slowly returned.

In this manner, opportunity for a very thorough study of the three types of sensibility was afforded. The result is a confirmation and considerable extension of the analysis of cutaneous sensibility previously made on other patients.

A similar but less extensive study of sensations following the division of a peripheral nerve has since been made at the Government Hospital for the Insane at Washington by Dr. Franz.³

MEDICINE AND THE LAY PRESS

The relations between medicine and the press form the subject of a thoughtful address¹ by Dr. G. W. Crile, before the Section of Experimental Medicine of the Academy of Medicine of Cleveland. To what is due, he asks, the changed attitude of the public and the press toward medicine, as evidenced in the desire for medical items, which leads the newspapers nowadays to invade the privacy of the physician; whereas, aforetime, it was a fair presumption that such items appearing in the newspapers were not likely to be spontaneous, but had their source in the inspiration of the medical man. Crile sees in this change a realization by the public of the fact that medicine, by the rising tide of science, has come almost unexpectedly into the gravest of responsibilities, both private and public, and finds itself wielding a new and mighty power, affecting not alone the ordering of the life of the individual, but much of the conduct of the municipality and the state. It is making possible a world-wide conquest of the tropics by the white man, influencing commerce and industry at large, and adding year by year to the expectancy of life. In appreciation of this work, the public has invested it with continually growing authority and responsibility, and has provided vast sums for it to be applied not only in the immediate relief and prevention of disease, but in study and research for further means thereof. It is but natural, therefore, that the public should feel itself interested in this great work that is being done under its auspices; and the profession, for its part, concedes the principle of publicity, in certain directions, in the public interest. Exception is taken rather to the form and to the matter of the publication of medical items than to such publication in itself. The trouble between the physician and the editor, in Crile's opinion, lies in a lack of editorial discrimination in the use of medical items and of the appreciation of the rights of physicians. It is clear, however, that it would be impossible in these days to keep medical items of interest from the press, and Crile asks whether, even if it were possible, it would be desirable to do so. The press may be the most powerful means of influencing the public in those beneficent lines so much desired by the medical profession. The employment of a staff physician, therefore, or the submission of medical news to reasonable supervision by an authoritative committee, is suggested by Crile as the means of satisfying the needs alike of the public and the press, without, at the same time, trenching on the rights of the physician.

It is to be remembered, in viewing this subject, that the objection to the publication of medical details rested on the individualistic basis of medicine. It was due almost solely to the likelihood of its abuse as a mode of advertising, and to the consequent insult to the profession as a body that such "commercialism" on the part of any of its members entailed. That objection

1. *Cleveland Medical Journal*, May, 1909.

still holds good, so far as the medical news relates to the professional capacity, status or doings of individual physicians. But with the growth of scientific medicine, the individualistic basis has been replaced by a communal one, and there has arisen, as Crile points out, a desire in the public for information as to the progress of this science, just as it desires information as to the progress of all other sciences. It is not only permissible, but even desirable, to gratify this natural curiosity, provided that in so doing the interests of the individual are not sought in place of those of the public and of the profession at large.

There is, however, a further limitation, arising out of a regard for the interests of the public itself. Some would reply that the public best knows its own interests. That is not entirely true. If it were, why pass laws to interfere with absolute freedom of contract in regard to hours and conditions of labor, and many other similar points that will readily suggest themselves? This limitation arises from the fact that premature or inaccurate publication of supposed medical discoveries may do infinite public harm in various ways; e. g., by arousing unrealizable hopes, and so causing naturally anxious invalids to postpone until too late the resort to measures of efficiency, and even, may be, to expose themselves in addition to actual and positive danger. Moreover, not only themselves, but many others also, may be thus exposed, through the creation of a sort of "boom" in unconfirmed and possibly altogether harmful practices, based on theories of the most nebulous nature or on observations or experiments full of inaccuracy or defective in method.

The problem is so to draw the line as to permit of giving the fullest and earliest accurate information to the public, without pandering to the self-seeker or exposing the public to these insidious dangers.

VOLUNTARY CLOSING OF MEDICAL COLLEGES

During the past five years no less than thirty medical colleges, either through merger or otherwise, have voluntarily closed their doors, such action being taken chiefly that higher standards of medical education might prevail. The majority of these were fairly strong schools, and to close them required many sacrifices on the part of their faculties; nevertheless that action was deliberately taken. This was true in Indiana, in Kentucky, in Ohio, at Minneapolis and at other places, and the spirit thus manifested is the greatest promise that fair educational standards will eventually be established throughout this country.

The reasons for the closing of these medical schools are practically the same as those clearly set forth by the dean of another college which has voluntarily closed its doors and which is referred to on another page.¹ The action taken by this Nebraska college is another step in

the progress being made toward fewer but better equipped medical schools. When it is considered that a few years ago this country had almost as many medical colleges as all the rest of the world combined and that in general the standards were decidedly lower than in other countries, the mere fact that the number of our medical schools is gradually being diminished is in itself encouraging. But the fact that the medical faculties themselves are voluntarily closing their colleges, or raising their standards, influenced only by their recognition of the needs of modern medical teaching, is far more important. Reforms that come voluntarily from the colleges themselves are bound to be more certain, more enduring and more in the development of an improved medical pedagogy.

The advancement of medical standards during the past few years has been remarkable, and we are now entering on what may prove to be a great era of reconstruction in medical education. The number of medical colleges in five years has been reduced from 166 to 148. On the other hand, with few exceptions, those which remain have been elevating their standards, improving their facilities and methods of teaching, and in every respect have developed into stronger medical schools. The number of medical schools requiring one or more years of college work for admission has increased in five years from 4 to 25 and will be further increased to 48 or 50 by next year.

But the goal is not yet reached. The spirit that has already been manifested by our medical teachers in subordinating personal interests for those of higher educational standards leads us to feel that in a very few years the medical schools of the United States will be equal, if not superior, to those of any other country.

GELATIN AS A FOOD IN INTESTINAL DISEASE

Gelatin belongs to the group of substances known as albuminoids. It resembles proteids in that it is converted into peptones by digestion, gives the biuret reaction and has many amino acids in common with proteids; it differs from them, among other ways, in not having certain molecules, the tryptophan and tyrosin radicles. It is easily digested and readily absorbed by the intestinal mucosa and to many persons is palatable in moderate quantities for a long period of time.

Years ago, Voit, and later Munk, found that, while gelatin was not able entirely to replace proteids, it had great value in sparing them, in this respect far surpassing fats and carbohydrates. More recently others have called attention to the food value of gelatin, especially in certain gastrointestinal diseases. Murlin¹ found that under certain conditions as much as 63 per cent. of the total nitrogen necessary for the body could be supplied in the form of gelatin. Herter² discusses

1. *Am. Jour. Phys.*, 1907, xix, p. 285.

2. *Infantilism from Chronic Intestinal Infection*. Macmillan Co., New York, 1908.

1. Department of Medical Education, this issue.

at considerable length its value as food and the advantages it possesses in inhibiting certain forms of intestinal decomposition. Proteids contain the tryptophan and tyrosin molecules, and these substances may give rise to harmful products in the intestinal canal. Tryptophan, for example, in the process of decomposition, forms skatol, indol and other products harmful in excessive quantities; from tyrosin arise phenol derivatives of several varieties which in case of excessive putrefaction may be formed and absorbed in quantities sufficient to produce symptoms of intoxication. Again, carbohydrates can not be tolerated at times because of the excessive fermentation which they induce.

Herter calculates that one ounce of gelatin will yield about 120 calories, or from 10 to 15 per cent. of the entire caloric requirements of the organism in twenty-four hours. This amount of gelatin may easily be added to the milk of a child during the period of twenty-four hours, which at times may be of the greatest importance for nutrition. By applying these facts in a practical way in the feeding in cases of infantilism caused by intestinal intoxication, Herter obtains results which appear to indicate that the value of gelatin in such cases is considerable. For instance, in cases of excessive fermentation in which carbohydrates can not be tolerated, gelatin added to milk, fermented in order to remove the sugar, is found to be an excellent food for the child and also decreases the intestinal decomposition. And on account of the absence of the tyrosin and tryptophan radicles in gelatin the phenol, indol and skatol derivatives may be diminished when it is used to replace the proteid constituents of the food. Thus, without decreasing the nutritive value of the food, the toxic products are greatly lessened.

It is interesting that some organisms (*Bacillus bifidus* and *B. infantilis*), commonly found in the intestinal tract and probably associated with certain gastrointestinal disturbances, will not grow on gelatin media even outside the body, while on carbohydrate and proteid media they flourish luxuriantly. This is another reason for the substitution of gelatin for carbohydrates and a portion of the proteids in infections of this character.

Herter summarizes the value of gelatin as a food thus: It has a considerable degree of caloric value; as a partial substitute for carbohydrates, fats and common proteids, it is valuable; it is incapable of undergoing putrefaction based on the presence of the tryptophan or tyrosin molecules; it is promptly absorbed; it is unable to support certain specific forms of bacterial life associated with certain intestinal diseases.

Medical News

ALABAMA

Convicted of Manslaughter.—Dr. W. L. Noel, charged with killing Jesse E. Roberts, town marshal of Boaz, is said to have been found guilty of manslaughter, May 1, and sentenced to imprisonment for seven years in the penitentiary. The usual notice of appeal was given.

Elections.—At the annual meeting of the Alumni Association of the Medical Department of the University of Alabama, Mobile, the following officers were elected: President, Dr. Samuel G. Gay, Selma; vice-presidents, Drs. Parker J. Glass, Mobile, and W. A. Sellars, Montgomery; secretary-treasurer, Dr. Percy J. Howard, Mobile, and orator, Dr. J. Maxwell Austin, Wetumpka.

ARIZONA

Antituberculosis Association Organized.—On May 22, the Arizona Association for the Study and Prevention of Tuberculosis, in affiliation with the national association, was organized with the following officers: President, Dr. John W. Foss, Phoenix; vice-presidents, K. C. Babcock, Tucson; Dr. John E. Bacon, Tombstone, and Rev. J. E. Critchfield, Phoenix; secretary, Dr. John W. Flinn, Prescott; treasurer, Lloyd Christy, Phoenix, and consulting medical board, Drs. Otto E. Plath, Phoenix; Harry T. Southworth, Prescott; W. Vincent Whitmore, Tucson, and William D. Cutter, Bisbee.

State Society Meeting.—The eighteenth annual meeting of the Arizona Medical Association was held in Prescott, May 18-20, and the following resolutions were unanimously adopted:

Stimulated by the clear and comprehensive study on preventive medicine given this morning by Dr. W. Jarvis Barlow, of Los Angeles, we, the committee appointed to draw up resolutions embodying his suggestions, submit the following:

1. *Resolved*, That the Arizona Medical Association recommends the formation of an Arizona Public Health Association, whose object shall be a study of public health problems, the education of the public and cooperation with the various boards of health of Arizona.

2. *Resolved*, That the Arizona Medical Association recommends the compulsory registration of all contagious and infectious diseases, including tuberculosis and compulsory vaccination of school children and systematic revaccination.

3. *Resolved*, That the Arizona Medical Association recommends that such legal steps be taken as will insure thorough inspection and regulation of the milk supply.

4. *Resolved*, That the Arizona Medical Association appoint a committee of five to report through its official organ, the *Practitioner*, and to the secretaries of the county societies, such information as they can obtain regarding public health legislation and organization and to formulate a definite program to lay before the constitutional convention of Arizona, and that on the recommendation of this committee a special meeting of the Arizona Medical Association be called to adopt such a program.

The following officers were elected: President, Dr. Robert N. Looney, Prescott; vice-presidents, Drs. John W. Foss, Phoenix; William D. Cutter, Bisbee, and Edward S. Godfrey, Tucson; secretary, Dr. John W. Flinn, Prescott; treasurer, Dr. Enoch B. Ketcherside, Yuma, and essayist, Dr. W. Warner Watkins, Phoenix. Phoenix was selected as the place of meeting for 1910.

CALIFORNIA

State Board of Health Appointed.—The governor has appointed the following members of the State Board of Health: Drs. Martin Regensberger, San Francisco; Wallace A. Briggs, Sacramento; Newell K. Foster, Oakland; Frank K. Ainsworth, San Francisco; W. Le Moyne Wills, Los Angeles, and James H. Parkinson, Sacramento.

Alumni Meeting.—At the annual meeting of the Alumni Association of the College of Physicians and Surgeons, San Francisco, May 18, the following officers were elected: President, Dr. Thomas Fletcher; vice-presidents, Drs. Frederick C. Keck, and C. O. Forester; secretary, Dr. Charles M. Troppmann, and treasurer, Dr. Charles A. Faulkner.

Hospitals.—Construction work on the Peninsula Hospital, Palo Alto, has been commenced. The building and grounds will cost \$60,000, and the building is expected to be ready for occupancy October 1.—The Dempsey Hospital, Vallejo, is being enlarged, and the new part of the building will contain seven rooms, including a large operating room and accessories.

Personal.—The Board of Health of Fresno has elected the following officers: President, Dr. Warden T. Bair; health officer, Dr. George H. Aiken, and bacteriologist, Dr. Grace Hopkins.—Dr. Neil F. Robinson, Monrovia, who has been seriously ill with appendicitis, is said to be improving.—Dr. Asbury N. Loper has resigned as city health officer of Fresno.—Dr. William J. Hosford, Alameda, is reported to be critically ill as the result of being run over by a bicycle.

State Board Appointed.—The following appointments of members of the State Board of Medical Examiners were announced by Governor Gillette, May 12: Drs. D. L. Tasker, Los Angeles; W. H. Stiles, San Bernardino; William M. Mason, Lodi; Charles Clark, San Francisco; Charles L. Tisdale, Alameda; J. Henry Barbat, San Francisco; William W. Rumble, Riverside; Walter Lindley, Los Angeles; Fred R. Burnham, San Diego; George F. Reinhardt, Berkeley, and W. W. Vanderburg, San Francisco.

Graduation Exercises.—The graduation exercises of the Oakland College of Medicine and Surgery were held May 27. The chief addresses were given by Hon. Henry A. Melvin, Dr. J. Wilson Shiels, San Francisco, and Rev. Homer J. Vosburgh. The commencement exercises of Cooper Medical College, San Francisco, were held May 11, when degrees were conferred by Mayor Edward R. Taylor, on a class of 21. The address was delivered by Rev. F. W. Clappott. A class of 11 was presented with diplomas at the thirteenth annual commencement exercises of the College of Physicians and Surgeons, San Francisco, May 19. The presentations were made by Dr. Winslow Anderson, president of the institution, and the doctorate oration was delivered by Hon. S. B. Woods.

DISTRICT OF COLUMBIA

Medical School Commencement.—The annual closing exercises of the Army Medical School were held May 29. A class of 29 was graduated, and the principal address was delivered by Dr. Roswell Park, Buffalo, First Lieutenant, Medical Corps, U. S. Army.

Hospital Contract Awarded.—The contract for the construction of the seven two and one-half story buildings for the Naval Medical School Hospital on the old observatory grounds, Washington, has been awarded to the Thompson-Starrett Co. for \$223,205.

Personal.—Dr. William C. Borden has been appointed dean of the Georgetown University School of Medicine, vice Dr. William F. R. Phillips, and Dr. John R. Wellington has been made clinical professor of surgery. Dr. J. C. Blackstone has been appointed physician to the poor, vice Dr. James A. Watson, retired.

ILLINOIS

Another Osteopathic Bill Defeated.—After one of the bitterest fights that has taken place in the House of Representatives this session, during which an unsuccessful attempt was made to remove the Secretary of the State Board of Health from the floor for leading the opposition to the bill, Senate Bill 351 failed of passage at 2:30 o'clock, May 30, four hours before the adjournment of the General Assembly. It appeared from the first roll-call that the bill had been passed. A verification was then demanded by the opponents of the measure, who charged that members who were not in the hall had been voted. The verified roll-call showed that only 63 members had voted for the bill, or 14 less than a constitutional majority. Senate Bill 351 was probably the most pernicious osteopathic measure ever introduced in Illinois. It aimed to confer on osteopaths "all the rights and privileges of physicians and surgeons"—to quote from the bill, and to require the State Board of Health to license certain osteopaths without examination.

Chicago

Drops Eclecticism.—Bennett College of Eclectic Medicine and Surgery announces officially the change of name to Bennett Medical College.

Fracture Clinic.—Dr. William Hesser conducts a fracture clinic every Saturday afternoon at 2:30 at Alexian Brothers' Hospital, corner Racine and Belden avenues, to which medical men are invited.

Illegal Practitioners Fined.—Mrs. C. Hanson and Stanislaw Sajowski, accused of practicing medicine without a license, are said to have been found guilty and fined \$100 each by juries in Municipal Judge Fry's court.

Personal.—Dr. and Mrs. Heman H. Brown have sailed for Europe. Dr. and Mrs. Arnold C. Klebs sailed for Europe May 23. Dr. Edward A. Fischkin has been elected president of the Chicago Hebrew Institute. Dr. William F. Rittenhouse has been elected president of the Menoken Club.

Zone of Quiet Invaded.—The superintendent of Wesley Hospital has made a protest to the Board of Education against the erection of a new school building on the block bounded by State, Dearborn, Twenty-fifth and Twenty-sixth streets, which is within the "Zone of Quiet" established around the Wesley Hospital.

MARYLAND

Personal.—Dr. Daniel B. Sprecher has been elected mayor of Sykesville. Dr. Victor F. Cullen has been re-elected superintendent of the Maryland State Sanatorium for Tuberculosis.

Bail Forfeited.—In the case of the State versus Dr. William B. Merritt, Easton, under indictment for criminal malpractice, and released on \$5,000 bonds, the defendant did not appear

when the case was called, May 25, and the bail was forfeited, the judge refusing to reduce the amount of the bond.

Legislation for the Insane.—The State Lunacy Commission has directed its secretary, Dr. Arthur P. Herring, Baltimore, to confer with the attorney general in drawing up two bills for presentation to the legislature; the first of which provides for an appropriation of \$400,000 for the erection of additional buildings for 400 new patients at the Springfield Hospital, and for the establishment of a special hospital for the negro insane; the second bill gives the Commission power to transfer insane patients from the county almshouses to the State Hospital, and makes it obligatory on county authorities to obey the orders of the Commission, and provides for supervision of the county asylums by the Commission.

Baltimore

Mayo to Lecture.—It is announced that Dr. Chas. H. Mayo, Rochester, Minn., on the invitation of the Faculty of Physic, will deliver a course of lectures at the University of Maryland in the fall on "Diseases of the Thyroid Gland."

Auxiliary Formed.—The wives of members of the Medical and Chirurgical Faculty of Maryland met at the new Medical Hall May 25, and organized the Ladies' Auxiliary of the Widows' and Orphans' Fund, and entered on an active campaign to raise a large fund, to be immediately available, for this excellent charity. The fund now amounts to \$1,074, invested in 5 per cent. securities; it is in the hands of the Faculty, and only the interest can be used for the charity.

Commencement.—The twenty-seventh annual commencement of the Woman's Medical College was held May 27. A class of 5 was graduated, and the address to the graduates was delivered by Dr. Howard A. Kelly. Dr. Guy L. Hunner, president of the board of trustees of the college, presided. The annual commencement exercises of the College of Physicians and Surgeons of Baltimore were held June 2. The University of Maryland, at its commencement, May 31, graduated a medical class of 89.

MASSACHUSETTS

Bequest.—By the will of the late William B. Rice, Quincy, \$20,000 is devised to the Quincy City Hospital, and the suggestion is made that \$200,000 be employed for the establishment of a hospital and home for aged, a home for unfortunates, or a technical school.

Society Meeting.—At the annual meeting of the Essex North District Medical Society, held in Lawrence, May 5, the following resolution was adopted: "The Essex North District Medical Society recommends to its fellows that when called to make an examination with other physicians of a case where testimony in court is likely to follow, they make this examination on the basis of a professional consultation." The following officers were elected: President, Dr. Charles E. Durant, Haverhill; vice-president, Dr. Warren W. Pillsbury, Newburyport; secretary-treasurer, Dr. J. Forrest Burnham, Lawrence; corresponding secretary, Dr. Roy V. Baketel, Methuen; auditor, Dr. William H. Merrill, Lawrence; supervising censor, Dr. Leyander J. Young, Haverhill; censors, Drs. Frank B. Pierce, Haverhill; Robert M. Birmingham, Lawrence; John A. Magee, Lawrence, and John A. Fitzhugh, Amesbury; councilors, Drs. Leyander J. Young, Haverhill; Israel J. Clarke, Haverhill; Charles G. Carleton, Lawrence; Frank M. Snow, Newburyport; J. Forrest Burnham, Lawrence; John A. Douglas, Amesbury; Ernest H. Noyes, Newburyport, and Frederick E. Sweetsir, Merrimac; commissioner of trials, Dr. John F. Croston, Haverhill; nominating councilor, Dr. Israel J. Clarke, Haverhill, and alternate, Dr. Charles G. Carleton, Lawrence.

NEW JERSEY

Camden Physicians Elect.—At the annual meeting of the Camden City Medical Society, Dr. William I. Kelchner was elected president; Dr. William H. Pratt, vice-president, and Dr. Joseph W. Martindale, secretary.

Addition to Sanatorium.—The authorities of the Newark Tuberculosis Sanatorium, which is located at Verona, have purchased for \$7,000 twenty-four and one-half acres to be added to the grounds of the institution.

NEW YORK

No Negligence Shown.—In the Supreme Court, April 8, the case of Charles Barton against Dr. John H. Martin, Binghamton, for \$5,000 damages for alleged malpractice, was decided in favor of the defendant, and motion for a new trial was denied.

Bequests to Hospitals.—By the will of the late Peter F. Collier, New York City, bequests of \$2,000 each annually for ten years were made to St. Joseph's Roman Catholic Hospital, Syracuse, and the Hospital for Incurable Consumptives in the Bronx.

New York City

Position of Pathologist Vacant.—The salaried position of pathologist in the German Hospital and Dispensary is vacant. Application with curriculum vitae may be sent to the president of the institution, Mr. August Zinsser, German Hospital, Seventy-seventh street and Park avenue.

Personal.—Dr. Hugh Angus Stewart, a graduate of Edinburgh, has been appointed adjunct professor of pathology in the College of Physicians and Surgeons.—Dr. Arthur H. Bogart was struck by a taxicab May 24, and suffered a fracture of the left leg and contusions all over the body.—Dr. Edward O. Park has been appointed attending physician of the fresh air department of the New York Association for the Improving of the Condition of the Poor.

Hospitals Benefited.—The Hospital Saturday and Sunday Association collected for the fiscal year \$85,752, or about \$2,000 more than for the preceding year. Of this amount \$72,000 was distributed among 43 hospitals in Manhattan and the Bronx. Montefiore Home and Hospital for Chronic Invalids received \$7,200; Mount Sinai Hospital \$7,200; St. Luke's Hospital, \$4,411; the German Hospital, \$3,439; the New York Infant Asylum, \$3,043; the Society of the Lying-in-Hospital, \$2,923; Hospital for the Relief of the Ruptured and Crippled, \$2,920, and the Post-Graduate Hospital, \$2,814. Eight additional hospitals received sums exceeding \$2,000, and seven others received over \$1,000. Smaller sums were divided among the remaining hospitals.

Quarterly Report of Bureau of Records.—This is a condensed quarterly report of the Bureau of Records, for the quarter ended March 31, 1909. The estimated population for the first quarter of 1909 was 4,564,792; for 1908, 4,422,685; the deaths in 1909 numbered 19,058; in 1908, 20,306; the death rate for 1909 was 16.94; for 1908, 18.43; the corrected death rates (non-residents and infants under one week not included) for 1909 was 16.04; for 1908, 17.24; the births in 1909 numbered 30,185; in 1908, 32,655; the marriages numbered in 1909, 9,632; in 1908, 9,557; the stillbirths in 1909 numbered 1,740; in 1908, 1,927. The total number of deaths in January, 1909, was 6,297; February, 5,743; March, 7,018; a total of 19,058, giving a death rate of 16.94 per 1,000 of the population against an average of 20.531 deaths and a death rate of 20.04 per 1,000 for the corresponding quarters of the preceding five years, a decrease of 3.10 points. If the numbers of deaths from the principal causes and at certain age groups are compared with those of the preceding quinquennial averages, corrected to correspond with the increase of population, the following increases and decreases will be found: Decreases—Typhoid fever, 23; smallpox, 1; measles, 33; scarlet fever, 54; whooping cough, 2; diphtheria, 80; influenza, 180; pulmonary tuberculosis, 323; other forms of tuberculosis, 57; meningitis, 305; cerebrospinal meningitis, 227; apoplexy, etc., 605—latter due to more accurate certification of cause of death—acute bronchitis, 180; lobar pneumonia, 890; bronchopneumonia, 140; diarrheal diseases under 5 years of age, 68; Bright's disease and nephritis, 306; old age, 79; violent deaths, 160 (deaths by accidents, 150; deaths by homicides, 20); congenital debility, 89; under 1 year of age, 404; under 5 years of age, 813; between 5 and 65 years, 2,320; 65 and over, 354. Increases—Cancer, 40; organic heart diseases, 156; suicides, 10.

NORTH CAROLINA

Commencement.—At the annual commencement of the Leonard School of Medicine of Shaw University, Raleigh, recently, a class of 23 was graduated.

Personal.—Dr. James R. Reitzel, High Point, was seriously injured in a runaway accident recently.—Dr. W. R. McCain, formerly of Waxhaw, S. C., has located at Charlotte.—Dr. E. C. Laird, formerly of Chase City, Va., has located at Greensboro.

District Society Meeting.—The third annual meeting of the Sixth District Medical Society was held in Chapel Hill April 29. Dr. George W. Long, Graham, was elected president; Dr. Isaac H. Manning, Chapel Hill, vice-president, and Dr. James M. Templeton, Cary, secretary.

State Society Meeting.—The annual convention of the Medical Society of the State of North Carolina will be held at the Battery Park Hotel, Asheville, June 15-17. The State Board of Medical Examiners will hold its annual examination at the same place, beginning June 9.

Communicable Diseases.—During April, 87 of the 95 counties of the state reported contagious diseases as follows: Measles, 29 counties; whooping cough, 47 counties; scarlet fever, 23 counties; diphtheria, 23 counties; typhoid fever, 25 counties; malarial fever, 6 counties; influenza, 18 counties; pneumonia, 63 counties; cerebrospinal fever, 4 counties; mumps, 5 counties; roseola, 1 county; chickenpox, 2 counties, and smallpox 22 counties.

Health Superintendents Elected.—Dr. James L. L. McCullers, McCullers, for Wake county; Dr. J. Rufus McCracken, Waynesville, for Haywood county; Dr. Daniel E. Sevier, Asheville, for Buncombe county; Dr. William S. Anderson, Wilson, for Wilson county; Dr. Marvin L. Smoot, Spencer, for Rowan county; Dr. Lawrie J. Arnold, Lillington, for Harnett county; Dr. John W. Wallace, Concord, for Cabarrus county, and Dr. J. K. Pepper, Winston-Salem, for Forsyth county.

Optometry Examiners Appointed.—The governor has appointed a state board of examiners in optometry as provided for by the recent session of the legislature. In the statute creating the board, optometry is defined as "the employment of any means other than the use of drugs, medicine or surgery for the measurement of the powers of vision, and the adaptation of lenses for the aid thereof." The passage of this act was unfortunate, will, it is believed, tend to lower the professional standard in the state, and emphasizes the need of alertness on the part of the legislative committee of the state society.

OHIO

Alumni Election.—At the election of the Starling-Ohio Medical College Alumni Association, May 18, Dr. A. C. Elder was elected president; Dr. Maybelle Richards, secretary, and Dr. Robert Drury, treasurer.

Tuberculosis Hospital to Be Erected.—It has been decided to erect a tuberculosis hospital for Franklin county to cost \$150,000, and to accommodate 150 patients. The present hospital is inadequate and there are already nearly 80 on the waiting list.—At a meeting of delegates from Montgomery, Preble, Greene, Miami, Darke and Shelby counties, held in Dayton, May 18, it was decided to establish a district tuberculosis sanatorium at the Brookside Sanatorium on the Covington Pike, near Dayton.

Commencement Exercises.—At the annual commencement exercises of the Cleveland College of Physicians and Surgeons, Medical Department of Ohio Wesleyan University, May 20, a class of 16 was graduated. The faculty address was delivered by Dr. Milton J. Lichty, and the commencement address by Rev. Frank W. Luce, and Rev. Herbert Welch, president of the university, presented the diplomas.—A class of 50 was graduated from the Starling-Ohio Medical College, Columbus, May 18. President O. W. Thompson of the Ohio State University presented the diplomas, and Rev. Washington Gladden delivered the annual address.

Personal.—Dr. Starling Loving, Columbus, of the class of 1849, Starling Medical College, was the guest of honor at the reunion and banquet of the class of 1898, May 18.—Dr. Edward V. Hug has resigned as a member of the staff of St. Joseph's Hospital, Lorain.—Dr. Ira J. Mizer, day physician at the state penitentiary, Columbus, has resigned.—Dr. Harry D. Belt, Kenton, has been commissioned Major Surgeon of the Second Infantry, Ohio N. G., vice Major Franklin B. Entrikin, Findlay.—Dr. E. H. Roriek, superintendent of the Athens State Hospital, has resigned.—Dr. John F. Jones, Columbus, has been made chairman of the Columbus-Lincoln Centenary Committee.

Cincinnati

Donation to Hospital.—Nicholas Walsh, Cincinnati, has donated \$1,000 to St. Elizabeth's Hospital to be used for the construction of a laboratory for the institution.

Personal.—At the meeting of the faculty of the Ohio-Miami Medical College, May 10, Dr. E. Otis Smith was elected secretary.—The Academy of Medicine on May 17, presented the names of the following ten physicians to the mayor, from which the new health board is to be selected: George A. Fackler, Julius H. Eichberg, Samuel E. Allen, Allan Ramsey, David I. Wolfstein, Charles H. Castle, Christian R. Holmes, John H. Landis, Alfred Friedlander, and John E. Griewe.

OKLAHOMA

Fires in State Asylum.—Fire at the Oklahoma Hospital for the Insane, Fort Supply, April 14, due to a prairie fire, destroyed several buildings and caused a loss of \$75,000. By the exertion of the attendants a panic was averted, and no casualty occurred. Another fire occurred a day or two later

which caused small damage, and a third fire, April 12, destroyed the main hospital building. No lives were lost, but it was necessary to carry 56 of the 59 patients out of the building.

OREGON

Commencement.—Degrees were conferred on a class of 15 graduates of the Medical Department of the University of Oregon by President E. L. Camp of the University, May 3.—The annual address was delivered by Prof. Samuel E. Elliott, and the charge to the graduates by Dr. Robert C. Yennet.

Personal.—Dr. Esther C. Pohl, health officer of Portland, has resigned.—Dr. and Mrs. Luther H. Hamilton, Portland, have returned from Europe.—Dr. John N. Smith, Salem, has been appointed physician of the state penitentiary.—Dr. Osmon Rees, Portland, has been appointed a member of the State Board of Medical Examiners, vice Dr. Byron E. Miller, Portland, retired.

To Build State Sanatorium.—The governor on May 22 announced the appointment of the following members of the tuberculosis commission: For four years, A. L. Mills, Portland, and Robert Booth, Eugene; two years, Mayor George F. Rogers, Salem, and Leslie Butler, Hood River. The commission will supervise the erection of a sanatorium for the treatment of tuberculosis, for which \$20,000 was appropriated by the legislature. The act also carries an appropriation of \$25,000 for maintenance of the institution.

PENNSYLVANIA

Susquehanna Officers Elected.—At the meeting of the Susquehanna County Medical Society, held in Montrose, May 11, the following officers were elected: President, Dr. H. Hewitt Hooven, Harford; vice-president, Dr. Asa L. Hickok, Rush; secretary, Dr. Edward R. Gardner, Montrose; treasurer, Dr. John G. Wilson, Montrose, and censors, Drs. J. G. Wilson, Abram E. Snyder, New Milford, and Arthur J. Taylor, Hopbottom.

Railroad Fatalities Increase.—The report of the state railroad commission on accidents on the railroads of Pennsylvania, during the three months ended March 31, shows a total of 1,999 casualties as compared with 1,998 in the corresponding quarter of last year. The fatalities number 236 as against 145 for the same period in 1908. Of the persons killed, 74 were employes, 5 passengers, and 144 trespassers. Of the injured, 1,369 were employes, 153 passengers, and 162 trespassers. As compared with a year ago there was an increase of 92.77 per cent. in the number of trespassers killed and a decrease of 31 per cent. in the grade-crossing fatalities.

Antituberculosis Campaign.—The North Penn Clinical Society has just closed a successful antituberculosis campaign of four weeks, the pioneer effort in that section along the lines of public education. The exhibit covered six towns in four weeks, the campaign opening at Quakertown, April 24, and closing at Lansdale, May 19, with a total attendance of 18,000. The exhibit remained two days in each town and included personal demonstrations during the day and lectures in the evening by the recognized state and national leaders in the work. The demonstrations were conducted by the various members of the society and local physicians. A number of the towns have followed up the work by organizing local societies to cope with local conditions. The executive committee of the society was as follows: Dr. Walter H. Brown, Richlandtown, chairman; Dr. Francis E. Borzell, Cressman, secretary and treasurer; and Drs. A. C. Biehn, Quakertown; Mahlon B. Dill, Perkasio; Alfred E. Fretz, Sellersville; LeRoy H. Saxe, Telford; Morris B. Oberholtzer, Souderton; and John J. Bauman, Lansdale.

Philadelphia

Typhus Patients Recovered.—The two men who came from Russia on the steamship *Russia*, April 11, and were seized with typhus fever soon after landing, were discharged from the municipal hospital, recovered, May 12.

Floating Hospital For Poor Babies.—Following the lead of Boston and other cities in the operation of a floating hospital for babies of the poor, plans are being made to start a similar institution in this city. One hundred children will be cared for daily on the ship. The total cost for the season is estimated at \$1,000. Mr. Robert K. Cassatt has offered the use of a properly equipped barge for the purpose.

College Commencement.—The fifty-seventh annual commencement of the Women's Medical College of Pennsylvania was held May 26, when 24 graduates received the medical degree and the annual address to the class was delivered by Dr. Frederick P. Henry. Dr. Clara Marshall, dean of the college,

delivered a congratulatory address, and Mary E. Mumford, president of the college, conferred the degrees.

Bequests.—The will of the late Samuel E. Appleton bequeaths \$10,000 to the Episcopal Hospital, to be used as an endowment for two beds as a memorial to his deceased wife. —The will of the late Anna N. Murpha bequeaths \$2,000 to St. John's Orphan Asylum; \$2,000 to St. Joseph's Orphan Asylum; \$2,000 to St. Vincent's Home; \$2,000 to the Little Sisters of the Poor; \$1,000 to the House of the Good Shepherd, and \$1,000 to St. Joseph's Home for Boys.

Ex-Resident Physicians Organize.—A reunion of former resident physicians of the German Hospital was held at the University Club, May 7. An organization was effected and the following officers were elected: President, Dr. Henry F. Payne; vice-president, Dr. Isador P. Strittmatter; secretary-treasurer, Dr. John C. Gittings, and historian, Dr. A. P. Miller. —The ex-resident physicians of the Samaritan Hospital, at a meeting held May 26, elected the following officers: President, Dr. William McKee; vice-president, Dr. William A. Hatcher; secretary and treasurer, Dr. Ernest B. Mongel.

Personal.—The medical and pharmaceutical fraternity of the Fifteenth Ward gathered at the home of Dr. Reuel Stuart, who has practiced medicine for fifty-four years in the city, in honor of Dr. Stuart's eightieth birthday anniversary.—Dr. Ferdinand G. Angeny, formerly of Philadelphia, but more recently of Phoenix, Ariz., has gone to Avon-by-the-Sea, N. J., for the summer, and will return to Phoenix, in September.—Dr. Alexander C. Abbott, chief of the bureau of health, has resigned to resume the duties of professor of hygiene and bacteriology in the University of Pennsylvania.—Dr. A. C. Abbott was presented with a handsome colonial clock by the attaches of his office on his retirement, June 1.—Dr. Charles R. Heed sailed for Europe May 26.—Dr. George L. Megargee was given a farewell dinner by his medical friends, May 26, and was presented with a silver loving cup.

Municipal Hospital Opened.—Philadelphia's new Hospital for Contagious Diseases, comprising a group of 46 buildings, located on a tract of 58 acres at Second and Luzerne streets, was opened for formal inspection by Mayor Reyburn and the Director of Public Health and Charities, Dr. Neff, June 1. At the present time 21 of the 46 buildings are completed and will be ready for occupancy July 1. The buildings yet to be built will be exact duplicates of the buildings now ready, with the exception of the administration building and storehouse. The administration building is a three-story brick structure, provided in the rear with a three-story storehouse, which contains an ice manufacturing plant with a capacity of ten tons a day. There are four general wards for scarlet fever patients, each two stories high, a private ward for pay patients and an observation building, comprising fourteen small houses under one roof. The buildings are connected by an outside corridor, several hundred feet in length, by means of which entrance may be made to any one building without passing through another. Six brick cottages are provided for the isolation of malignant cases. Each is a hospital in itself with a ward for two to four beds; has a separate entrance and is provided with a nurse's room and diet kitchen. The observation building contains 14 miniature hospitals under the same roof, each separated from the other. These will be used to observe patients until a positive diagnosis has been made, when they will be transferred to their special department. The wards are so lighted that direct rays of light never fall on a patient.

TEXAS

Sanitarium Located.—The locating committee of the West Texas Baptist Sanitarium has decided to accept the bid made by Stamford, which offered \$56,000.

District Society Meeting.—At the annual meeting of the Northwest Texas Medical Association, held in Mineral Wells, April 20, Dr. Wade H. Walker, Wichita Falls, was elected president; Dr. Harold L. Warwick, Fort Worth, vice-president, and Dr. E. Perry Bass, Mineral Wells, secretary.

Ambulance Companies.—Under the reorganization of the medical corps of the Texas National Guard, San Antonio, Dallas and Houston are named as district headquarters, at which detachments of the hospital corps composed of twenty men each will be established. The detachment in San Antonio is under the command of Capt. Robert L. Dinwiddie, M.D.; that in Dallas is commanded by Lieut. Fred B. Johnson, M.D., and that in Houston by Major J. Lindsey Short, M.D.

UTAH

Hospital Notes.—Mrs. Thomas D. Dee, Ogden, has decided to build a hospital in that city in memory of her husband, to cost at least \$100,000, and to accommodate from seventy-

five to one hundred patients.—Drs. Thomas G. Odell, Murray, and Hardie Lynch, Salt Lake City, have leased and reopened the Murray General Hospital.

Health League Organized.—The Utah Health League, the object of which is to promote public health through sanitation and the prevention of disease, has been organized in Salt Lake City with the following officers elected by the board of directors: Dr. James E. Talmage, Salt Lake City, president; Dr. Fred E. Clark, Logan, vice-president, and Mrs. C. H. McMahon, Salt Lake City, secretary-treasurer.

State Board Election.—At a recent meeting of the newly appointed Board of Medical Examiners of the State of Utah, the following officers were appointed: President, Dr. David C. Budge, Logan; secretary, Dr. George F. Harding, Salt Lake City, and treasurer, Dr. Amasa S. Condon, Ogden. The regular meetings of the board of examiners are held on the first Monday of January, April, July and October.

Personal.—Dr. Herbert S. Pyne, Provo, has been elected secretary and executive officer of the Utah County Board of Health. The other medical members of the board are Drs. J. Franklin Noyes, American Fork, and Albert G. Stoddard, Spanish Fork.—Dr. George A. Dickson, Ogden, has been elected physician of the State Industrial School, his term of office to begin July 1.—Dr. Raymond J. Powers, Ogden, had a narrow escape from death April 15, by accidentally taking a large amount of carbolic acid.—Dr. Daniel H. Calder has been reappointed medical superintendent of the State Mental Hospital, Provo.

VIRGINIA

Sanatorium Opened.—The Johnston-Willis Sanatorium, completed at a cost of \$75,000, was opened for patients May 25. The hospital will accommodate 55 patients and will be under the charge of Drs. George B. Johnston and A. Murat Willis.

Commencements.—The seventy-first annual commencement exercises of the Medical College of Virginia, Richmond, were held May 19, and a class of 49 was graduated. Dr. Christopher Tompkins, dean of the faculty, delivered the faculty address, and the annual address was delivered by President Charles H. Denny, Washington and Lee University.—The annual commencement exercises of the University College of Medicine, Richmond, were held May 18, when a class of 41 was graduated. Joseph D. Eggleston, Jr., superintendent of public instruction, addressed the graduating class, and Dr. Stuart McGuire, president of the college, gave the faculty address.

Personal.—Dr. Stuart McGuire has been re-elected president of the board of trustees of the University College of Medicine, and Dr. John Dunn, secretary-treasurer.—Dr. Lewis C. Boshier has been re-elected president, and Dr. Charles R. Robins, secretary-treasurer of the Memorial Hospital Corporation, Richmond.—Robert F. Williams, superintendent of the State Sanatorium for Tuberculosis, has resigned.—Dr. S. H. Burton, Parnassus, has been elected district councillor.—Dr. S. Harrison Smith, Alexandria, who is now in Panama, has accepted a position as physician to a railway company in Brazil.—Dr. William F. Creasy, Newport News, has succeeded Dr. William F. Cooper as state quarantine officer.

WASHINGTON

Personal.—Dr. William L. Hall has retired as president of the board of health of Spokane.—Dr. John H. O'Shea has succeeded Dr. Burchard H. Roark as physician in charge of the Spokane City Emergency Hospital.

New Medical Society.—A medical society has been organized, consisting of physicians of Green Lake, Fremont, Ballard and University district of Seattle, with Dr. Josiah L. Millett, Mountainview, as temporary president, and Dr. Harry C. Dyer, Green Lake, as temporary secretary.

State Board Appointed.—The governor has appointed the following as the State Board of Medical Examiners: Drs. Frank P. Witter, Spokane; Edward J. Taggart, Bremerton; A. Macrae Smith, Bellingham; Howard R. Keylor, Walla Walla; E. Weldon Young, Seattle, and George H. Dow, Chehalis.

Medical Department of Alaska-Yukon-Pacific Exposition.—Dr. Edmund M. Rininger, in charge of the medical department of the Alaska-Yukon-Pacific Exposition, Seattle, announces that a modern equipped emergency hospital has been installed, and that a room has been set aside for visiting physicians where they may receive their mail, write letters, etc. He invites physicians visiting the exposition to have their mail sent in care of the Emergency Hospital.

Unlicensed Doctors Immune.—Judge John B. Yakey, of the King County Superior Court, decided, on May 16, that curative

theories of any character for the relief of human diseases may be put in practice in the state of Washington between that time and June 12, without requiring license from the State Medical Board. The decision was in the case of J. Meacham and Ronald Strath, charged with practicing medicine without license, and the court sustained the demurrer of the defendants, which resulted in the dismissal of the charge.

Hospital News.—Plans are being prepared for the additions to the new Fannie C. Paddock Memorial Hospital, Tacoma. The entire institution, when completed, will consist of nine buildings, and will have cost about \$300,000.—By the will of the late Mrs. Henry Fuhrman, \$10,000 is bequeathed to the Orthopedic Hospital, Seattle.—The new hospital for the Seattle Children's Home was formally opened May 4. The building has been erected at a cost of \$7,500, and is designed as an isolation hospital for contagious diseases. There are six beds in the dormitory and two separate wards, besides a sun room, physician's room, etc.

CANADA

Hospital News.—A woman's hospital has recently been established in Toronto by the Salvation Army, and another is to be established in Montreal, of which Dr. A. Lorne Gilday will be superintendent.

Tuberculosis Institute.—The Tuberculosis Institute has recently been chartered at Montreal. Dr. W. H. Drummond is president of the organization and Drs. Thomas G. Roddieck, E. Persillier La Chapelle, and J. George Adami are vice-presidents.

Personal.—Dr. Frederick P. Drake, London, has been selected to represent the Ontario Medical Association at the International Medical Congress, Bucharest.—Dr. Edward W. Archibald, Montreal, has started for Naples.—Drs. Walter W. Chipman and J. R. Goodall, Montreal, have returned from Europe.—Drs. John L. Day and Hyman Lightstone, Montreal, have gone abroad for study.—Dr. Alexander McPhedran has been elected president of the Toronto Academy of Medicine.

Antituberculosis Convention.—The ninth annual meeting of the Canadian Association for the Prevention of Tuberculosis was held in Hamilton, May 20, and the following physicians were elected officers: President, Dr. J. George Adami, Montreal; vice-presidents, Sir James A. Grant, M.D., Ottawa, and Drs. Louis Laberge, Montreal; Gordon Bell, Winnipeg; and J. A. Hutchinson, Montreal; and lecturer, Dr. George D. Porter, Toronto. The name of the association was changed from the Canadian Association for the Prevention of Tuberculosis and Other Forms of Tuberculosis to the Canadian Association for the Prevention of Tuberculosis.

GENERAL NEWS AND COMMENT

Jefferson Alumni Elect.—The fourth annual meeting and banquet of the New England Association of Jefferson Medical College graduates was held in Hartford May 26. The following officers were elected: President, Dr. Adam S. McKnight, Fall River, Mass.; vice-president, Dr. John T. Farrell, Providence, R. I.; secretary, Dr. Angus MacOdrum, Boston, and treasurer, Dr. Whitfield N. Thompson, Hartford.

Much Quinin Used.—During the calendar year of 1908 more than a ton and a quarter of quinin was used by the department of sanitation in the Canal Zone for the prevention of malaria by administrative prophylactic doses, to supply a tonic to the employes, and in the treatment of the 12,372 cases in the hospital, and the 23,000 cases in the sick camps. Quinin is dispensed free to any one who applies for it, whether he be an employe of the commission or not.

Pediatricists' Election.—At the annual meeting of the American Pediatric Association, held in Lenox May 25 and 26, the following officers were elected: President, Dr. David L. Edsall, Philadelphia; vice-presidents, Drs. D. J. Miller, Atlantic City, and Edward W. Saunders, St. Louis; secretary, Dr. Samuel S. Adams, Washington, D. C. (re-elected); treasurer, Dr. Charles H. Dunn, Boston, and recorder and editor, Dr. Linnaeus E. La Fetra, New York City. Washington was selected as the next place of meeting.

Tuberculosis Foes Elect.—At the annual meeting of the National Society for the Study and Prevention of Tuberculosis, held in Washington May 13-15, the following physicians were elected to office: President, Dr. Edward G. Janeway, New York; second vice president, Dr. Henry Sewell, Denver; secretary, Dr. Henry Barton Jacobs, Baltimore; treasurer, Dr. George M. Sternberg, Washington, D. C., and executive committee, Drs. William H. Baldwin, Washington; Herman N. Biggs, New York City; George M. Kober, Washington; John H. Lowman, Cleveland, Ohio, and Joseph P. Walsh, Philadelphia.

Health in the Canal Zone.—During March, there were 4 deaths among white employes in the Canal Zone, equivalent to an annual rate of 3.90 per 1,000. During the same month there were 32 deaths among the total force, equivalent to an annual rate of 8.76 per 1,000. Including the civil population of the zone, there were 72 deaths, equivalent to a death rate of 11.67 per 1,000, and taking the total population, there were 184 deaths or an annual mortality of 17.05 per 1,000. The constantly-sick rate of 20.60 per 1,000 is very small as compared with the statistics of similar bodies of men elsewhere.

Personal.—Dr. Walter B. Swift, Boston, was elected president of the Anglo-American Medical Association of Berlin, April 17, and has taken the apartment of the late president, Dr. Honan, at 78 Lutzowstrasse.—Dr. Raymond F. Bacon of the chemical division of the Bureau of Science, Manila, is spending five months in the United States.—Dr. Elijah J. Neathery, Sherman, Texas, has been made one of the vice-presidents of the Frisco System Medical Association.—Dr. A. E. Mayner, acting health officer at Panama, sailed for the United States May 4, and Dr. John G. Evans has been detailed as acting health officer during his absence.—Drs. John L. Phillips, Ancon; M. E. Connor, Cristobal, and F. R. Curney, Corozal, have been elected officers of the Canal Zone Branch of the American National Red Cross.

Mortality Statistics.—In the annual report of the census bureau covering 1907, it appears that during the registration area including 15 states and 76 large cities, there were 687,034 deaths, the death rate being 16.5 per 1,000 as compared with 16.1 per 1,000 for the year before. The highest death rate, 18.6 per 1,000, is reported from California, and New Orleans is said to have had the highest city death rate, 24 per 1,000, Denver coming next with 23.25 per 1,000, followed by Fall River, Mass., with 22.25, and Washington with 20.3 per 1,000. In every instance the cities had larger death rates than the country. Chief among death causes were pneumonia, tuberculosis, heart disease, violence, intestinal diseases and kidney diseases in the order named. Marked increases were shown in deaths from influenza, pneumonia and heart disease. The deaths of children under five years of age made up 26.8 per cent. of the total, and 19.1 per cent. was made up of deaths of infants under one year of age.

National Purity Congress.—The fifth annual congress of the National Purity Federation will be held in Burlington, Iowa, October 18-22. The officers of the association are: President, B. S. Steadwell, Lacrosse, Wis.; vice-presidents, Dr. Howard A. Kelly, Baltimore, and Hon. Ben B. Lindsey, Denver; corresponding secretary, Miss Julia E. Morrow, 104 Ralph street, Spokane, Wash., and treasurer, Charles A. Mitchell, Cherokee, Okla. The object of the congress is to secure the cooperation of all societies, national, state and local, that are considering the promotion of purity in the life of the individual and in social relations, and inaugurating a forward movement to arouse the conscience of the people to organized vice and the operations of its promoters, and assure to all a high standard of morality and a right knowledge of the pure life. A general invitation is extended to all interested in the cause, and organizations are requested to send delegates to the congress.

Health of the Philippine Islands.—During the fourth quarter of 1908, the acting director of health in the Philippine Islands, reports that there were 7,330 cases of cholera in the provinces with 4,292 deaths, equivalent to a death rate of 58.55 per cent. These cases were from 29 provinces and 186 municipalities, the largest number of cases and the lowest death rate being in northern Visaya. Cholera became epidemic in Manila in September; the maximum number of cases was reached September 20, when sixty cases were reported. Twelve days later the daily number of cases was reduced to five, and the epidemic may then be said to have been eradicated. The cases that appeared in December were probably due to infection introduced from Rizal provinces. The principal factor in the difficulty encountered in the eradication was insanitary conditions, namely, lack of sufficient public closets, lack of sufficient public hydrants, lack of proper street drainage, and insanitary nipa shacks in the district. During the quarter 24 lepers were transferred from San Lazaro Hospital, 2 from Mindoro, 4 from Romblon, and 97 from Cebu to the Culion Leper Colony.

Typhus and Bad Economic Conditions in Russia.—A moving account of conditions in Russia is presented in a long letter from Moscow in the *Münchener med. Wochenschrift*, May 18, signed by Dr. A. Dworetzky. It states that the epidemic of typhus which has been raging in Russia during the last few months, and which has cost the lives of so many physicians and nurses, far surpasses the cholera epidemic both in its extent and intensity. The waves of the epidemic are growing constantly higher and spreading to new regions, as he shows by the official statistics from Astrachan, Odessa, Charkow, Kiev, and a dozen other widely scattered departments. Besides exanthematous typhus, relapsing fever and typhoid are making numerous victims. In Moscow alone there were 773 cases of typhus last November and December, January and February, and 1,223 of relapsing fever. In the Charkow district there were 1,880 cases of typhus during the last two months, with 3,150 cases of typhoid and 575 cases of relapsing fever. There are at present in the overcrowded Charkow hospitals 400 typhus or typhoid patients. All this epidemic of typhus and typhoid is unmistakably the result of conditions in the prisons, which even the authorities admit. In 1896 the prisons contained an average of 85,000 inmates, but ten years later, he says, "after the 'freedom' and 'constitution' manifestoes," the number of inmates jumped at once to 111,500; in 1907, it was 138,500; in 1908, 181,000, and the authorities estimate it at 200,000 at present. The appropriations for the current year for the salaries of officials and other expenses of the prisons are \$15,300,000, half as much as is paid out for educational purposes. About three millions are for the pay-roll and 789 additional prison guards have been appointed this year. In contrast to these sums, the budget called for \$3,570,000 for the support of the 200,000 prisoners, which averages less than \$1.53 per capita a month. The report recently prepared by a committee of the Duma in regard to conditions in the prisons states that exanthematous typhus is prevailing at present in sixty-five different prisons and is spreading thence to the general populace. The government issued a decree April 15, forbidding the physicians connected with the prisons, under penalty of discharge, to say anything to outsiders in regard to the health conditions of the inmates of the prisons. He adds the figures in regard to the number of persons hung; it has increased from 10 in 1905 to 825 in 1908, according to official statistics; the daily papers give the figure of 1,831 for the last two years. Suicides are occurring in constantly increasing numbers, not only among those condemned to death, but also in the general populace, the number recorded by the daily papers in 1908 averaging 239 a month. In the current year there were 352 in January and 364 in February—the list including all ages, from children of 10 to the very old. In St. Petersburg alone there were 1,442 suicides last year. He mentions in conclusion a decree recently issued by the chief magistrate of Odessa forbidding the use of any anesthetic except chloroform or ether, owing to the recent death of a patient under ethyl chlorid.

Isolation of Lepers in Japan.—The Japanese government has roused to the necessity of caring for the numerous lepers, and

our exchanges state that five leper colonies are to be organized and several thousand lepers in advanced stages of the disease are to be segregated. A leper hospital is to be provided at Osaka and a leper colony with asylum on the island of Kiu Siu.

Fine for False Medical Certificate.—A Berlin court recently imposed the mildest penalty, one month's imprisonment, on a physician who certified that an employee in a government office had influenza and was too sick to return to work for a week, when the truth was that the girl had just been delivered of a child. He claimed in his defense that the girl was actually too ill to return to work, and that he merely misstated the cause of her illness, which defrauded no one. The letter of the law, however, had to be upheld, and the mildest penalty was imposed, the judge expressing regret that he was unable to make it still lighter.

LONDON LETTER

(From Our Regular Correspondent)

LONDON, May 22, 1909.

Friendly Societies and the Income Limit in Australia

A chronic struggle has gone on for some years between the medical profession in England and the "friendly societies" on the question of an income limit. For the small sum of about \$1 per annum a member of a "friendly society" is insured against the cost of medical attendance and medicine. The societies consist principally of workingmen who would under ordinary circumstances be unable to pay for anything like a prolonged medical attendance. Physicians who have not a wealthy *clientèle*, i. e., the majority of the profession, willingly undertake attendance on these terms which are not unremunerative compared with other poor-class practice, especially in the large towns where the working class much resort to hospitals in cases of serious illness and accidents. But sometimes friendly societies have a few wealthy members with annual incomes as high as \$5,000 or more who, under present conditions, are entitled to attendance for the small insurance. The profession has always resented having to attend them, but is powerless to refuse. An income limit above which a member would be unable to secure attendance on the club terms has been long suggested and is advocated by the British Medical Association and other medical societies, but the friendly societies have always preserved an obstinate resistance and regarded the suggestion as an unwarrantable interference with their management. They adopt the position that the physician must carry out his contract and that if he objects to the terms he can resign and that they will have no difficulty in finding a successor. At the antipodes the same struggle exists and the problem is even more serious, for there the friendly societies contain a large number of wealthy men. The British Medical Association of New South Wales has put forward the claim that in future the medical officers of friendly societies should not be compelled to attend members whose income exceeds a certain sum which has been decided as a fair one. The restriction is not to apply to the present members of the lodges, but only to those who may join in future. But the societies show no signs of yielding.

The Metropolitan Provident Medical Association

This association for many years has done good work by arranging for the medical attendance of members of the working class on a provident system. On payment of a subscription of about \$1 per annum a man or woman is entitled to medical attendance and the necessary medicine. In the case of a family a reduction is made in this rate. There are now 20 branches—16 dispensaries and 4 medical clubs, with a membership roll of 12,040. The association is almost self-supporting, receiving only a small grant from the Hospital Saturday Fund. The extension and development of the provident system appears to be the only barrier against the indiscriminate free treatment of the working class. It is thought desirable to make some modification of the present rules to meet the need which has been shown to exist for medical treatment among the 750,000 children of the school age in London. If this is not done school clinics under the management of the educational authorities will sooner or later be established. This prospect is viewed with great misgiving, and it is felt that the association should make every effort to prevent further relaxation of the sense of parental responsibility with its consequent effect on character. But the strong tendency to socialistic legislation which now exists is more likely to injure than to be stemmed by the provident system.

Total Abstinence and Longevity

The United Kingdom Temperance and General Provident Institution, an insurance company, has two departments—one for total abstainers and one for users of liquors. As the statistics of these departments are kept separately they afford a useful means of comparing the mortality of total abstainers with that of the general population. The report for the year 1908 shows that in the temperance section 457 claims were expected according to the ordinary life tables, but only 274 were made; whereas, in the general section 461 claims were expected and 407 were made. Thus the proportion of actual to expected claims in the former was only 46 per cent. as compared with 64 per cent. in the latter. The large sum of \$250,000 was thus saved in the temperance section and goes to swell the bonuses of the corresponding policy holders. Though both classes of lives showed good results there was a marked advantage in the case of total abstainers. These results are open to one criticism: Decisive as they are in showing the superior longevity of total abstainers, they are not decisive in proving the superiority of total abstinence; for those who adopt total abstinence are always prudent persons who regulate their lives in other ways much more carefully than the general population.

PARIS LETTER

(From Our Regular Correspondent)

PARIS, May 20, 1909.

The Treatment of Ophthalmia Neonatorum

Professor Motais, of Angers, has just made, at a session of the Academy of Medicine, an interesting communication on the treatment of ophthalmia of the newborn. In place of silver nitrate, which must be used in elevated doses and is not without danger, Motais makes use of protargol, which he prescribes in the following fashion: After a simple washing with the eyelids widely opened, with a tampon of absorbent cotton moistened with a solution of potassium permanganate, 2 drops of collyrium of protargol, 1 to 5, are instilled into each eye. This instillation is repeated every three hours, night and day, until the secretion becomes scanty and less thick. The instillations are then made every six hours; and at the end of 5 or 6 days, when the secretion has become very weak and the swelling of the eyelids no longer exists, the collyrium of 1 to 5 is replaced by one of 1 to 10. If the cornea is ulcerated before the treatment the protargol immediately checks the destructive process and institutes from the next day on, cicatrization of the ulcer.

The academy has authorized the midwives themselves to make use of Credé's method, and to give an instillation of 2 per cent. silver nitrate solution to the newborn at the moment of birth. In point of fact, they have this solution at their disposition, and it is to be feared that they do not resist the temptation to continue the treatment themselves should ophthalmia declare itself. Therefore, Motais thinks, with some justice, that it would be prudent to leave in their hands only a solution of protargol, 1 to 5, which is innocuous while being perfectly active.

The Chair of Anthropology at the Museum

Dr. Verneau, assistant professor of anthropology at the Museum of Natural History, has been appointed professor of this chair in succession to Professor Hamy, deceased.

Death of Ernest Besnier

Dermatology has just lost one of its most illustrious representatives in France, Dr. Ernest Besnier. Born at Honfleur, April 21, 1831, hospital interne in 1853, doctor in 1857, he won at the *concours* in 1863 the position of physician of the hospitals. For ten years he devoted himself to study of general medicine and of hygiene. It was at this period that he published in Dechambre's *Dictionnaire encyclopédique des sciences médicales* a series of very remarkable articles. At the same time he laid before the *Société médicale des hôpitaux*, whose general secretary he was for a long time, annual reports of epidemics. As a hygienist, he wrote on the laws which govern epidemics; on glassmakers' syphilis; on the adulteration of foodstuffs, and on parasitic affections and their treatment—works which in 1880 gained him a membership in the Academy of Medicine. Ernest Besnier became physician of St. Louis Hospital in 1872, and thenceforward devoted himself entirely to the study of dermatology. He published many original papers in the *Annales de dermatologie et de syphiligraphie*, which he founded with his friend, Dr. Doyon. In collaboration with the latter, he published in 1881 the French edition of Kaposi's "Lessons on the Maladies of the Skin," enriched by numerous remarkably precise notes.

His talent and his vast erudition marked Besnier out for a chair in the College of Medicine, to which he was nominated; but an unforeseen ministerial change allowed politics to deprive the Paris College of Medicine of an eminent master. Dr. Besnier did not protest, but continued for years to give instruction at the St. Louis Hospital. Of irreproachable scientific and professional probity, Ernest Besnier remains a model of the physician faithful to his duty.

Election of Professor Brissaud to the Academy of Medicine

During its last session the Academy of Medicine elected an honorary member in the section of medical pathology to replace Professor Joffroy, who died last November. Dr. Brissaud, professor of internal pathology at the College of Medicine and physician at the Hôtel-Dieu, was elected by 54 votes against 5 for Dr. Babinski and 1 for Dr. Gilbert Ballet.

A Monument to Michael Servetus

In 1906 a committee was formed, consisting of Professor Osler, Lombroso, Brouardel, Brissaud, Dejerine, Charles Richet and others, to erect at Vienne, in the department of the Isère, August 14 next, a monument to Michael Servetus, who was a precursor of Harvey, through his description of the circulation of the blood in his book "Christianismi Restitutio," published in 1553. Professors Lortet, Mairet and Charles Richet, for the committee, whose headquarters is at the city hall of Vienne, Isère, issue a final appeal to the public.

The International Tuberculosis Society

In May, 1910, this society, under the presidency of Dr. Lancereaux, will distribute to the authors who submit the best works on tuberculosis the following prizes: (1) one of \$60; (2) one of \$20; (3) two of \$10 each; (4) two gold medals with a diploma of honor; (5) three silver medals with diploma of honor. Authors who wish to enter this contest should send their essays under sealed cover before Jan. 1, 1910, to Dr. George Petit, secretary-general of the International Tuberculosis Society, rue du Rocher, No. 51, Paris.

Inauguration of the Bligny Sanatorium

The bureau of popular sanatoriums of Paris, on the 9th of May, inaugurated at Bligny, near Versailles, its new institution for tuberculous women and young girls. A men's sanatorium, having 124 beds, has been in operation there since 1903. The sanatorium just inaugurated has 120 beds, giving a total of 244. Unlike Germany, where the organization of sanatoriums has developed remarkably, France possesses only 12 sanatoriums for tuberculous adults with a total of 860 beds. All these institutions are due to private initiative, with the exception of the sanatorium at Angicourt (148 beds), belonging to the Assistance publique.

Death of Dr. Dujardin-Beaumetz

Dr. Dujardin-Beaumetz, former medical inspector general of the army, died at Montpellier, where his military career began. As a *médecin-major* in 1870, he was taken prisoner at Sedan. On his release he immediately took service in the army of the Loire. In 1885 he directed at Tonkin the sanitary service of the expeditionary corps. On his return from Tonkin, Dujardin-Beaumetz was called to the post of director of the sanitary service at the ministry of war, which he occupied from 1887 to 1895. He rendered important services, notably in the judicious measures prescribed by him in the fight against typhoid fever in the army.

Dr. Maurice de Fleury Elected to the Academy of Medicine

At its last session, the Academy of Medicine proceeded to elect an associate member in succession to Dr. Hamy, deceased. On the first ballot Dr. Maurice de Fleury, author of many works on neuropathology and psychology ("Introduction à la médecine de l'esprit," "Le Corps et l'Âme de l'enfant," "L'Âme du criminel," etc.), was declared elected by 51 votes, against 21 for Dr. Voisin, 9 for Dr. Castex, 6 for Dr. Capitan and 2 for Dr. Valude.

BERLIN LETTER

(From Our Regular Correspondent)

BERLIN, May 14, 1909.

Cultivation of *Spirochæta Pallida*

Although the etiologic significance of *Spirochæta pallida* for syphilis is recognized at the present by the great majority of dermatologists and bacteriologists, there is still lacking the

final proof, namely, the cultivation of the disease producers and the production of the disease by infection with the cultivated germ as proof of the etiologic relation of the pathogenic bacterium as it was furnished for the tubercle bacillus in a classical way for the first time by Robert Koch in 1882. Repeated attempts to cultivate the spirochete have been made since the discovery by Schaudinn in 1905, but so far without success. In the last number of the *Deutsche medizinische Wochenschrift*, a young bacteriologist, Dr. Schereschewsky, reports an apparently successful result of cultivation. He succeeded in securing a growth of the spirochete at 37 degrees C. in from three to five days on horse serum which had been brought to gelatinous consistency and subjected to a partial autolysis, by standing about three days in a thermostat at 37 degrees C. By dark-field illumination, as in stained preparations, the author could establish the identity of the spirochete forms grown by him (and which are figured in the article) with the *Spirochæta pallida*. To be sure, he has not succeeded so far in obtaining a pure culture of the spirochetes, but he could determine that they were motile even on a solid medium. Schereschewsky will continue his investigations at Neisser's clinic and will next undertake injections in apes.

The Tipping Business

In regard to this notorious affair, I am able to report a satisfactory outcome in one respect. May 10 a private damage suit by Professor Senator against the editor of a Berlin sensational paper, on account of an article published therein, was tried, and as a result of the expert opinions of Professors Hiss and Goldscheider, an agreement was reached by which the accused editor admitted that he was convinced that the small and occasional sums paid by Professor Senator had not the character of tainted money or of commissions. The accused further assumed the costs of the proceeding. It is to be expected that a similar result will be reached in the remaining proceedings, this affair of Senator's, namely, the trial before the court of honor and the university authorities, which have been inaugurated at the request of the professor himself with the consent of the minister of education, and that Senator at least will come out of the whole affair exonerated, although it must be admitted that he has been somewhat incautious. Whether the other specialists will be able to justify themselves to an equal extent remains to be seen.

A Prussian Professional Ordinance for Medical Men

It is of special interest in connection with the foregoing, that the executive committee of the Prussian medical councils has just published an ordinance for regulating the professional relations of Prussian physicians, which is to be submitted to all the Prussian medical councils for discussion and determination. In a number of the German states there have been for some time ordinances of this sort. The Prussian medical councils have also for the most part adopted such regulations for the physicians of their own district. While there are no essential differences between these codes, there are some inequalities, and from a practical standpoint it is very desirable that a uniform code should be adopted for the entire profession of Prussia, so that what is regarded as permissible in one district should not be condemned in another, and vice versa. It would take too much space to give the entire proposed code, but I will mention the principal points which I assume will be of particular interest to American physicians, as it is well known that strict ethical principles are observed in their professional intercourse. Public advertisement and even private offer of medical services are forbidden. In this are included signs of private dispensaries, as well as those indicating hours for free treatment, the recommendation of private methods in the public papers, reports of cases in lay periodicals and the publication of testimonials. However, the beginning, interruption and resumption of practice, change of residence, etc., may be publicly announced for a few times. The owners of sanatoria and similar institutions may be permitted frequent notices in the newspapers by the executive committee of the medical councils. In addition, the buying and sale of medical practices, as well as the agency for such transactions, are forbidden; likewise, the treatment of patients exclusively by mail; also giving testimonials for secret remedies or for medicines in general for the purpose of commercial advertisement. A physician is not permitted to treat patients in conjunction with laymen. Offering or assuring advantage of any sort to a third person, as a midwife, porter, etc., in order to secure practice is not permissible. It is allowable to remit the fee in whole or in part to patients without means, but not to

those who are able to pay. The title of specialist is allowed only to a physician who has secured a thorough education in his specialty and who devotes himself particularly to it. Unfavorable criticism of a physician before the public is forbidden. Patients who are receiving medical treatment at their home may have the advice of other physicians only in case of imminent danger, and in that case the physician who was treating the patient at first must be notified in due time. Patients who are received by a *loem tenens* must be transferred to the principal on his resumption of practice. Written contracts or oral arrangements of any sort with private or public corporations must be submitted to an appropriate committee of the medical council for their sanction before they are finally signed, renewed or extended. This code will be discussed by the medical councils at their next sessions; without doubt criticism will be offered in most cases as to one or other of the conditions, as each council is sovereign in this respect. Time will tell whether the executive committee will succeed in harmonizing the various wishes of the councils so as to secure a single code agreeable to all of the councils.

Pharmacology

GLYCOZONE

Report of the Council on Pharmacy and Chemistry, with Comments

A number of specimens of Glycozone purchased in the open market were examined by a sub-committee. The product was found to be a mixture of approximately 90 per cent. glycerin, 5 per cent. glyceric acid, a small amount of water and traces of undetermined matter. The absence of hydrogen peroxid or other peroxids was demonstrated.

In its report the sub-committee held that: (1) The name of the product is objectionable and misleading; (2) the statements made in regard to its composition also are misleading; (3) the claims for its therapeutic value are exaggerated and untrue. Since the objectionable statements have been given wide publicity among physicians as well as among the laity, the sub-committee recommended that attention should be called to the matter in *THE JOURNAL*.

The report of the sub-committee was adopted by the Council.
W. A. PUCKNER, Secretary.

COMMENT:—While the name gives the impression that ozone or some similar substance is an essential constituent of Glycozone, or else that the preparation is a compound or derivative of ozone, and while the earlier advertisements stated that Glycozone was "glycerin combined with ozone," the examination made by the Council shows that there is no basis of fact for such inferences.

In the advertisements the "chemical formula" $C_3H_5O_4 + C_3H_5O_3$ appears under the word Glycozone. From the Council's report it is apparent that $C_3H_5O_4$ stands for glyceric acid and the $C_3H_5O_3$ for glycerin, and, therefore, indicate the chief constituents of Glycozone. Few, doubtless, would recognize the first formula as being that of glyceric acid, a product practically unknown in medicine, nor would many associate glycerin with the second. The evident intent is that physicians should accept the formula as a badge of respectability.

According to the label on a trade package, Glycozone is "prepared only by Charles Marchand, chemist," and is "an absolute cure for dyspepsia, catarrh of the stomach, ulcer of the stomach, heart-burn," etc. The label further reads: "This remedy is positively harmless. By destroying the microbian element in the stomach it prevents the fermentation of food and stimulates digestion." An examination of medical literature fails to reveal any basis for these claims. While glycerin possesses some antiseptic properties, it is evident that the glycerin which constitutes 90 per cent. of this remedy is not the agent that gives the glycozone such phenomenal virtues. General literature contains nothing that would indicate that glyceric acid in any quantity, with or without glycerin, possesses these miraculous properties. If by "microbian element" is meant microbic organisms, the statement is without foundation. There is nothing in this product which possesses these bactericidal powers.

The circular which accompanied a trade package, envelopes the preparation in an air of mystery. Derivation from, or close relation to, ozone and hydrogen peroxid is vaguely hinted at, without definite assertion. Thus, the chief therapeutic properties of glycozone and hydrozone are compared as follows:

"Hydrozone instantly destroys the microbian element, leaving the tissues beneath in a healthy condition."
"Glycozone acts more slowly, but not less certain as a stimulant to healthy granulations."

There is no similarity between the action of hydrozone, which is a hydrogen peroxid preparation, and glycozone, which consists of a mixture of glycerin and glyceric acid. The representation is false and misleading. The following statement, also, is an unwarranted exaggeration of the facts:

"As an internal medication in fermentation of food, catarrhal and inflammatory conditions of the stomach, and intestinal disorders, its action is prompt and effective, giving immediate relief to the patient."

The following is another illustration of the vague statements made: After asserting that glycozone is hygroscopic and that it will deteriorate by absorption of water unless securely corked, it is stated that "Its healing properties increase with age." Whatever mysterious ingredient there may be present in this mixture to justify the statement that the healing properties increase with age can only be conjectured. To humbug the patient further he is advised to use only a "silver, glass or hard rubber spoon."

MIGRAININ

Report of the Council on Pharmacy and Chemistry Rescinding Acceptance of the Preparation

The Council having voted to rescind the acceptance of Migrainin and to omit it from New and Nonofficial Remedies (Appendix), directed publication of the report given below.

W. A. PUCKNER, Secretary.

SUPPLEMENTAL REPORT ON MIGRAININ

To the Council:—Koechl & Co., American agents for Migrainin (Meister Lucius & Bruning) asserted that this preparation was a mixture of antipyrin 85 parts, caffeine 9 parts and citric acid 6 parts. The experiments of F. Zernik (*Apoth.-Ztg.*, 1906, p. 686), however, showed that Migrainin consisted of antipyrin 90.88 parts, caffeine 8.4 parts and citric acid 0.45 parts. When the attention of Koechl & Co. was called to this they informed the Council, on June 20, 1907, that the formula they gave was given them direct by the manufacturers abroad and that they, Koechl & Co., did not question its accuracy. They, however, offered to "write abroad and have the manufacturers confirm the formula as given." On July 23, 1907, Koechl & Co. wrote the secretary of the Council that the manufacturers had informed them that Migrainin contains 90 per cent. antipyrin and 9.1 per cent. caffeine citrate. This being an acknowledgment that the former statement submitted was incorrect, the Council voted that the approval of Migrainin should be reconsidered. Examination of the product, therefore, was taken up in the Association's laboratory and an original specimen, purchased in Chicago, was found to contain moisture 0.7 per cent., antipyrin 90.93 per cent., and instead of caffeine citrate 9.1 per cent., citric acid 0.51 per cent., caffeine 8.53 per cent. This analysis agreed essentially with the composition of Migrainin as found by Zernik.

1. Caffeine citrate is readily hydrolyzed by water, but in the dry form the existence of three caffeine citrates is possible as follows:

- (1). $C_8H_{10}N_4O_{12} \cdot C_6H_8O_7$ contains 50.28 per cent. caffeine.
- (2). $(C_8H_{10}N_4O_2)_2 \cdot C_6H_8O_7$ contains 66.91 per cent. caffeine.
- (3). $(C_8H_{10}N_4O_2)_3 \cdot C_6H_8O_7$ contains 75.18 per cent. caffeine.

If the "caffeine citrate" in Migrainin is present as in (1) there should, according to the statement of the manufacturer, be present 4.57 per cent. caffeine; if as in (2), 6.08 per cent. caffeine; if as in (3), 6.84 per cent. caffeine: the quantity found is 8.53 per cent. If the caffeine citrate is present as in (1), the citric acid present should be 4.53 per cent.; if as in (2), 3.02 per cent., and if as in (3), 2.26 per cent.: the citric acid found equals 0.51 per cent. This shows that the most recent statement of the firm, viz., that Migrainin contains 9.1 per cent. caffeine citrate, is incorrect, no matter what interpretation is given to the meaning of the term caffeine citrate.

While the discrepancies between the statement of the firm and the facts are perhaps not great, nevertheless they show that even the formula last given is incorrect, and that the statements of Koechl & Co., while no doubt made in good faith, were in this instance unreliable.

In recent advertising matter issued by Koechl & Co., "phenozon-cafein citrate" is given as a synonym for Migrainin, one circular stating that "Migrainin is phenozon-cafein citrate," etc. In the same circular the following also appears: "In the treatment of migraine with phenacetin or antipyrin, the attack is delayed, while with Migrainin it is usually permanently stayed." This will, no doubt, lead physicians to infer that Migrainin is not a mixture of antipyrin and cafein citrate, but that it is some new compound. While the firm disclaims any intention to mislead, it does not offer to withdraw or modify this circular. It is recommended, therefore, that the approval of Migrainin be rescinded and that it be omitted from New and Nonofficial Remedies.

SALIT

Report of the Council on Pharmacy and Chemistry Rescinding Acceptance of the Preparation

The Council was advised that Salit (Heyden Chemical Works), a preparation which previously had been approved, was being advertised to the public in Germany, and that it therefore should be classed with "patent medicines" intended for popular use. The following report was presented by a subcommittee:

SUPPLEMENTAL REPORT ON SALIT

To the Council:—The secretary reported to the Council that Salit is advertised to the laity abroad, but that the manufacturer had agreed that these advertisements should not appear in those foreign papers which are shipped to this country. The Council decided that in accordance with precedent the advertising of products in foreign lay journals should be held a conflict with the rules, and it voted that the acceptance of Salit be reconsidered. It is now recommended that Salit be refused recognition, and that it be omitted from New and Nonofficial Remedies.

The report was adopted by the Council and its publication directed.
W. A. PUCKNER, Secretary.

Association News

THE ATLANTIC CITY SESSION

Final Announcements for the Session to be Held Next Week

As this issue of THE JOURNAL reaches its readers, members of the Association are preparing to start for Atlantic City or are already on their way, while the Atlantic City profession is resting from its labors of preparation in anticipation of a most successful meeting.

The House of Delegates will be the first body to convene, and it will attempt to complete a considerable amount of work on Monday. It meets in the solarium of the Hotel Traymore. Its first session is at 10 a. m., June 7, and there will be presented the reports of the various officers and of the standing and the special committees.

The first and only General Session will be the Opening Meeting to be held in the Auditorium on Young's New Pier at Arkansas Avenue and the Boardwalk, Tuesday, June 8, at 10:30 a. m. At this meeting, after the addresses of welcome and reports of the committees of arrangements, the president-elect, Dr. W. C. Gorgas, Chief Sanitary Officer of the Isthmian Canal Commission, Ancon, Panama, will be installed into office and will deliver his address.

Tuesday afternoon the various sections will take up their work at 2 o'clock. The preliminary programs of these sections were printed in THE JOURNAL May 1. Each member is given, on registration, a copy of the official program, which details the proceedings at these section meetings, and gives abstracts of the papers so that all may know the scope of the articles to be read.

The Daily Bulletin

The A. M. A. Daily Bulletin will be issued on Tuesday, Wednesday and Thursday mornings with a list of names of those registered on the preceding day, and also with announcements of the events on the day of issue.

Mail Matter for Those in Attendance

Members should have their mail addressed to them in Atlantic City in care of the hotel in which they will stop. Those who neglected to secure hotel accommodations in advance may have mail addressed to them in care of the American Medical Association, Young's Old Pier, Atlantic City, N. J. A branch postoffice will be in operation adjoining the Bureau of Registration and the Scientific Exhibit and the Commercial Exhibit. There will also be telegraph and telephone booths, and a well-prepared Bureau of Information, whose attendants will be ready to answer questions on all points of interest.

Program of Entertainments

[The official members' badge, or one of those provided for ladies and guests, will be required for admission.]

TUESDAY, JUNE 8

4 to 5:30 p. m.—An informal tea will be given at the Chalfonte Hotel to the visiting ladies of the American Medical Association by the ladies' committee of Atlantic City.

7:30 p. m.—The Section on Nervous and Mental Diseases will give a dinner at the Hotel Marlboro. Members desiring to attend this dinner are requested to notify the chairman of the section at the Hotel Marlboro on Tuesday at noon.

7:30 p. m.—Harvard University alumni meeting and dinner at Hotel Windsor.

8 p. m.—Vanderbilt University Medical Department alumni banquet at Young's Hotel.

8:30 p. m.—Medico-Chirurgical College (Philadelphia) alumni reunion and smoker at Hotel Rudolf.

8:30 p. m.—The Section on Laryngology and Otology will hold an informal sea-food banquet, with vaudeville, at Hotel Rudolf. Price per cover, \$4.50. Those desiring to attend this dinner should notify the secretary of the section in ample time.

9 p. m.—Dartmouth Medical College alumni reunion at Hotel Chelsea.

9 p. m.—Jefferson Medical College alumni reunion and smoker at Hotel Royal Palace.

Alumni reunions for the medical departments of the University of Vermont and the University of Minnesota and for the Long Island Medical College and Tufts' Medical School to be announced later.

WEDNESDAY, JUNE 9

12 noon.—For visiting ladies: Exhibition of rescue by the Atlantic City Life Guards, directed by Beach Surgeon Dr. J. T. Beckwith, on beach opposite Tennessee avenue.

2:30 to 5:30 p. m.—Sailing parties for ladies will leave Ventnor Boat Club House at short intervals.

6:30 p. m.—"Wiener Studenten" will hold a reunion, supper and smoker at Old Vienna. Those intending to be present, address Dr. William N. Senn, Marlborough-Blenheim Hotel.

8:30 to 10 p. m.—Reception to the President, Dr. William C. Gorgas at Music Hall, Steel Pier.

10 to 12 p. m.—Dancing at Music Hall, Steel Pier.

THURSDAY, JUNE 10

11:30 a. m.—Public exhibition, hauling of seine (courtesy of Mr. John L. Young) at Young's Million Dollar Pier.

12 noon.—Alpha Omega Alpha Medical Scholarship Society members will meet for lunch; place to be announced later in the Bulletin.

4 to 6 p. m.—Ladies' reception at Plaza, Marlborough-Blenheim.

8:30 to 10:30 p. m.—Musical at Marine Hall, Steel Pier.

8:30 to 10:30 p. m.—Musical (Metropolitan Orchestra, with soloists), at Music Hall.

10:30 to 12 p. m.—Vaudeville and smoker for ladies and gentlemen at Islesworth Café, Virginia Avenue and Boardwalk.

10:30 to 12 p. m.—Vaudeville and smoker for ladies and gentlemen at New Berkeley Café, Kentucky Avenue and Boardwalk.

The Country Club House at Northfield will be open to the physicians and ladies during the entire meeting.

The Atlantic City Yacht Club extends the courtesy of its club house during the entire meeting.

The Meeting Places

The following are the meeting places announced by the Atlantic City Committee on Arrangements. It is to be noticed

that the Section on Practice of Medicine is to meet in Marine Hall, Steel Pier, in place of Casino Hall, Steel Pier, as first announced.

HOUSE OF DELEGATES—Tidymore Solatium.
BOARD OF TRUSTEES—Marlborough-Blenheim (Committee Room).
JUDICIAL COUNCIL—Marlborough-Blenheim
REGISTRATION—Young's Old Pier.
POSTOFFICE, TELEGRAPH, TELEPHONE AND BUREAU OF INFORMATION
—Young's Old Pier.
COMMERCIAL AND SCIENTIFIC EXHIBIT—Young's Old Pier..

SECTIONS

PRACTICE OF MEDICINE—Marine Hall, Steel Pier.
SURGERY AND ANATOMY—Ocean Hall, Steel Pier.
OBSTETRICS AND DISEASES OF WOMEN—Casino Hall, Steel Pier..
DISEASES OF CHILDREN—First Presbyterian Church, Pacific and
Pennsylvania Avenues
NERVOUS AND MENTAL DISEASES—Brighton Casino
PHARMACOLOGY AND THERAPEUTICS—Jewish Synagogue, Pacific and
Pennsylvania Avenues.
HYGIENE AND SANITARY SCIENCE—Baptist Church, Pacific Avenue,
near Pennsylvania Avenue
PATHOLOGY AND PHYSIOLOGY—Central M. E. Church, 1213 Pacific
Avenue
OPHTHALMOLOGY—Parochial Hall No. 1, Top Floor, Tennessee and
Pacific Avenues
LABORATORY AND OTOTOLOGY—Parochial Hall No. 2, Second Floor,
Tennessee and Pacific Avenues
CATAPHORIC MEDICINE AND SURGERY—Olivet Church, Tennessee and
Pacific Avenues
STOMATOLOGY—Olivet Church Sunday School Rooms, Tennessee and
Pacific Avenues.

Clinics in Philadelphia

The following clinics in Philadelphia for visiting physicians are announced in addition to those detailed in THE JOURNAL, May 22, page 1682:

METHODIST HOSPITAL, BROAD AND WOLF STREETS Friday, June 11

10:00 a. m.—Dr. J. Torrence Rugh. Excision of Knee.
2:30 p. m.—Dr. Walter Roberts. Adenoids and Tonsils.
3:00 p. m.—Dr. Philip H. Moore. Foreign Bodies in the Eye.

Saturday, June 12

10:00 a. m.—Dr. James Hendrie Lloyd. Demonstration and Lecture on Nervous Diseases
11:00 a. m.—Dr. Alfred Hand. Wound Walk
11:00 a. m.—Dr. Harlan Shoemaker. Surgical Pathology of Uterine Cancer
1:00 p. m.—Dr. Levi J. Hammond. Operative Surgery of Gall Bladder.

AMERICAN ONCOLOGIC HOSPITAL, 45TH AND CHESTNUT STS Daily

2:00 p. m.—Cases Treated by Tonic or Cataphoric Surgery by Dr. G. Betton Massey
3:00 p. m.—Surgical Cases by Dr. Addinell Hewson and Dr. Samuel McClary
4:00 p. m.—Cases Treated by X-Rays and Radium by Dr. William S. Newcomet
4:00 p. m.—Medical and Pathologic Demonstrations by Drs. Charles A. E. Codman, John M. Swan and C. B. Longenecker.

Correspondence

A Home for Aged and Disabled Physicians

To the Editor:—In connection with the home for old and disabled physicians suggested by Dr. Magruder (THE JOURNAL, May 22, 1909, p. 1682) let me say that at one of our Christian County Medical Society meetings in 1908 the proposition to build such a home in Kentucky was made and the secretary of this society was requested to communicate with every other society in the state and to put the matter before them. This was done and a resolution to that effect was also passed at our state meeting at Winchester in October last. A committee (of which I am chairman) was appointed to investigate the matter and to report to our state meeting in 1909.

We now have in the hands of every county secretary in this state subscription lists, with letters and subscription blanks, soliciting initial subscriptions of \$10, and \$5 annually. These are to be collected by me and made the basis of my report to the Kentucky State Medical Society in October.

If we could make this a national home instead of a state affair I believe it would be better. From present indications I believe the Kentucky physicians are going to build their home. I agree with Dr. Magruder that "the matter of planning the institution on such broad lines that provision might

be made for the care of the families of those who seek its shelter is one that should be given the most careful attention."

J. PAUL KEITH, M.D.

Secretary Christian County Medical Society, Hopkinsville, Ky.

The Philadelphia Branch of the American Pharmaceutical Association

To the Editor:—In connection with its exhibition of drugs and pharmaceutical processes at the meeting of the American Medical Association, in Atlantic City, the Philadelphia Branch of the American Pharmaceutical Association will hold a scientific meeting for the purpose of presenting and discussing papers on topics relating to the U. S. Pharmacopeia, National Formulary and New and Nonofficial Remedies. The meeting will be held on Friday morning, June 11, and will be in charge of the officers of the Philadelphia Branch. The following is a partial list of the papers that will be presented:

"U. S. Pharmacopeia and National Formulary Preparations versus Nostrums," by Mr. Otto Raubenheimer, Brooklyn.

"The Relation of New and Nonofficial Remedies to the U. S. Pharmacopeia," by Mr. M. I. Wilbert, Washington, D. C.

"Improvements in the National Formulary," by Mr. George M. Beinger, Camden, N. J.

"The Tests of the U. S. Pharmacopeia," by Prof. I. V. S. Stanislaus, Philadelphia.

Other papers, the titles of which have not yet been announced, but which are related to the foregoing topics, will be presented by Prof. Joseph P. Remington of Philadelphia and Prof. H. P. Hynson of Baltimore. The various papers will be discussed by prominent pharmacists and physicians. Invitations to attend this meeting are extended to all who are interested in improving the standard formulas for medicinal preparations.

ANDROSE HUNSBARGER, Secretary, Philadelphia.

The Danger of Heavy Nitrogenous Diet in Tuberculosis

To the Editor:—I wish to call the attention of the profession to the grave danger of a too heavy nitrogenous diet in tuberculosis. My attention has recently been called to several cases of albuminuria and nephritis with tuberculosis, coming on after the patient had been on a diet consisting of eggs and milk in large quantities. A patient may believe that he is doing the right thing in consuming a dozen or more eggs per day when insidiously there develops a pronounced albuminuria and perhaps along with this a tuberculous kidney infection. When the kidney elimination is impaired such patients fail very rapidly and frequently this disturbance of the kidney function seems to be the beginning of the end.

F. J. WALTER, Roswell, N. Mex.

The Combined Course

To the Editor:—I much regret that in my paper on "The Combined Course Leading to the Degrees of A.B. or B.S. and M.D.," in THE JOURNAL, May 22, the quotation marks were omitted by the compositor from the quotations inserted. It is not fair to an author to quote separate paragraphs from a number of separate articles so as to make it appear that they constitute a continuous statement. In my paper each paragraph quoted should have been indicated as a separate quotation.

JOHN M. DODSON, Chicago.

Hat-Pin in the Male Urethra

To the Editor:—I wish to report a case similar to the case of Dr. Hazzard (THE JOURNAL, May 29, p. 1759). A man 60 years old, was referred by Dr. Louis Burekhart of this city. He had a 6 inch plain headed hat-pin engaged in the urethra, which had been introduced in an effort at masturbation. It was removed exactly as in Dr. Hazzard's case; the point having almost entirely penetrated the penile body, the puncture was completed, the pin drawn through, and the direction reversed to push the head forward and out at the meatus.

FREDERICK R. CHARLTON, Indianapolis.

Book Notices

DANTE: PHYSICIAN. By A. G. Drury, M.D., Cincinnati, Professor of Hygiene in the Medical College of Ohio. Cloth. Pp. 89. Price, 50 cts. Cincinnati: The Lancet-Clinic Press, 1908.

This little book is one of the latest, as it is one of the most analytically just appreciations of the great Florentine poet, and shows a wide range of research, not only into the literature, but into the history of the Dante epoch. The net result is to establish the fact that Dante was not only a politician, a poet and a learned theologian, but a physician who was fully abreast of the science of his times. The text of the *Vita Nuova*, the *Convito* and the *Divine Comedy* has been searched and made to yield a thousand or more intrinsic evidences of Dante's complete mastery of everything relating to medicine in the thirteenth century. Every student of Dante will be interested in this new marshaling of old facts which, by their new association, have come to have a new significance.

DANIEL DRAKE AND HIS FOLLOWERS. Historical and Biographical Sketches by Otto Juettner, A.M., M.D. Royal 8vo, pages 496. Illustrated. Price \$5. Cincinnati: Harvey Publishing Company, 1909.

The medical profession of the United States should greet with satisfaction the appearance of this work which does justice, as justice has never before been done, to the memory of one of the greatest medical characters of the nineteenth century. Daniel Drake was born in 1785 and died in 1852. His life, identified almost entirely with Cincinnati, is an essential part of the history of that city; but his activities reached beyond his city and state. He was a scientist in a broad sense of the word; he was a physician, not only of deep thought, but of almost prophetic insight into the problems of his profession; he was an originator, a builder of institutions and of communities; and he was a citizen who recognized and responded to every civic obligation.

These various attributes viewed in the light of their detailed manifestations, comprise the great body of Dr. Juettner's book, which, not only to the physician interested in his profession, but to the citizen interested in his country, reads like a romance of the realistic school. It is important to emphasize the realism of the book, for in its pages Drake is not a mere steel engraving—although an excellent one of him forms the frontispiece—but here he walks and talks, teaches and preaches, loves and hates, a veritable human being with a full assortment of human characteristics. Here you can shake hands with him, talk with him and know him and realize that he is all the time worth knowing.

Dr. Juettner in this work has exemplified an important principle that is new in the development of polybiographies. He has taken Drake as his strong initial character and has traced the influences that have emanated from him and that have largely co-ordinated the medical activities, not only of Cincinnati, but of an important part of the entire country for a whole century. In doing so he has given the history of every man who has been identified with medical Cincinnati during all that long period. In this way one encounters in this book the names and portraits of Gofroth, Eberle, Moorhead, Slack, Mussey, Shotwell, Delamater, Locke, Wright, Comegys, the Lawsons, Gross, Parker, Rogers, McDowell, Rives, Tate, Blackman, Graham, Armor, Bartholow, Conner and R. C. S. Reed, a group of which the last named is the only survivor. The history of medical institutions and of the contemporary profession of Cincinnati is traced with accuracy. This is not a work filled with the usual fulsome praise of its subjects, but one written in excellent literary form and with a just critical appreciation of the facts presented. It is, therefore, a distinct contribution to the history, not only of the medical profession, but of the country.

HINTS TO SHIPS' SURGEONS. By J. F. Elliott, L.R.C.S., L.R.C.P. Cloth. Pp. 64. Price, 2s. London: John Bale, Sons & Danielson.

A useful little book for those who wish to sail as surgeons from English ports. It gives practical suggestions on the method of procuring an appointment as a ship surgeon; duties at sea; what to do in various emergencies; the matter of fees; and a list of the shipping lines from England carrying passengers and surgeons.

PURE MILK AND THE PUBLIC HEALTH. A Manual of Milk and Dairy Inspection. By Archibald Robinson Ward, B.S.A., D.V.M., Assistant Professor of Bacteriology and Director of the State Hygienic Laboratory, University of California, Berkeley, Cal. With Two Chapters by Myer Edward Jaffa, M.S., Professor of Nutrition and Director of the State Food and Drug Laboratory, University of California. Cloth. Pp. 218, with illustrations. Price, \$2. Ithaca, N. Y.: Taylor & Carpenter, 1909.

The improvement of the milk supply is receiving much attention in this country at this moment, and the relative merits of certified, inspected and pasteurized milk are widely discussed, especially by physicians. The appearance of Professor Ward's book, therefore, is most opportune. After a general exposition of the origin of bacterial contamination of milk and the changes in milk caused by bacteria, Ward devotes two chapters to the discussion of epidemic diseases transmitted by milk, and gives special attention to the transmissibility of bovine tuberculosis to man. This most important and much-debated subject is treated with conservatism and impartiality, and a sane attitude in regard to it is taken. Since opinions as to the frequency of transmission are still divided, the correct course to be pursued is to take no chances, but to prevent as far as possible the distribution of milk containing tubercle germs. The only successful means to accomplish this object lies in the application of the tuberculin test.

The chapters on the municipal sanitary control of milk and on pasteurization are of special interest. Pasteurization is ably defended on the grounds of protecting consumers against pathogenic bacteria and as a step toward an ideal milk supply. In the chapter on the microscopic analysis of milk, attention is given to the danger of drawing fallacious conclusions from the presence of streptococci and leucocytes in milk, and the colony count is shown to be the most valuable method of controlling milk supplies. An interesting account is given of the present status of milk commissions, their objects, methods and the results accomplished. The chapters on the analysis and adulteration of milk by Professor Jaffa are useful additions, especially for those actively engaged in this work.

The information which may be gathered from this book is invaluable for all those interested in the all-important and difficult movement toward a sanitary milk supply.

T. E. K. A.—JARLIBRO, 1909. Vol. I. Eldonita de la Tutmonda Esperanta Kuracista Asocio. Kun la portreto de l'honora prezidanto de la T. E. K. A., Dr. L. L. Zamenhof. Pp. 66. Paper. Price, 0.4 sm (20 cents). Köttschenbroda-Dresden: H. F. A. Thalwitzer, 1909.

This is the first year-book of the World Association of Esperantist Physicians, an association inaugurated at the Fourth International Esperantist Congress at Dresden, August, 1908. It contains a preface by Dr. Zamenhof, an account of the origin of the association, by the president, Professor Dor, of Lyons, and a summary by the secretary, Dr. Robin, of Warsaw, of what the association has accomplished. The list of officers and members occupies 23 pages, the total number of members at the date the book went to press being 428, though it is said that some hundreds have been since added. Dr. H. F. A. Thalwitzer writes on "Esperanto and the Red Cross," and Dr. F. Uhlmann-Huttwil on "Esperanto Medical Nomenclature." A table of national moneys, and their relation to the international money system devised by the Esperantists, is added. The booklet contains a portrait of Dr. L. L. Zamenhof, inventor of the language.

HUMAN PHYSIOLOGY. An Elementary Text-Book of Anatomy, Physiology and Hygiene. By John W. Ritchie, Professor of Biology, College of William and Mary, Virginia. Cloth. Pp. 362, with illustrations. Price, 80 cts. Yonkers-on-Hudson, New York: World Book Co., 1909.

As a text-book for children in the public schools, this volume is necessarily elemental. In common with most books for the purpose, the use of alcoholic beverages is uncompromisingly condemned. The chapter on "consumption" emphasizes the importance of good food and fresh air in treatment. A chapter devoted to accidents gives a brief description of the methods of resuscitating persons apparently drowned, stopping bleeding from an artery, treating sunstroke, burns, etc. The book contains practical suggestions and is to be commended.

PARCIMONY IN NUTRITION. By Sir James Crichton-Browne, M.D., LL.D., F.R.S., Lord Chancellor's Visitor in Lunacy, London. Cloth. Pp. 111. Price, 75 cents. New York: Funk & Wagnalls Co., 1909.

This book is frankly polemical. It is a reply to the arguments of Horace Fletcher and of Professor Chittenden of Yale, who maintain that much less proteid food is needed than is prescribed in the standard diets of Voit and Atwater.

Chittenden's experiments and conclusions are interesting and the latter tempting to the medical man who frequently has to prescribe for patients with stomach disorders and who has learned that he can contribute greatly to their comfort and ultimately lead them to recovery chiefly by curtailing the quantity of food which they eat. Crichton-Browne's arguments are chiefly these: "First, that it is an initial objection to Chittenden's view which is not easily met that it contravenes all human experience." The standard diets of Voit and Atwater represent the average usage of civilized men; at least those of Europe and America. Crichton-Browne has collected statistics which seem to show that even in Japan to-day practically the same proportion of nitrogen per pound of body weight is consumed as would be used on Voit's standard. He raises the question whether the long ages during which they have been vegetarians has not led to their diminutive stature, apparently forgetting that Buddhists in China and India are large men but have been as strict vegetarians for as long or a longer time.

The second contention is that a diet rich in proteids makes for physical and mental energy.

Third, Crichton-Browne points to the ill effects, both mental and physical, of the insufficient diet of English prisons, where the proteids are furnished in about the quantity prescribed by Chittenden or a little larger. But he overlooks the fact that in diets one and two of the prisons the total calories is too small and may account for the ill condition of prisoners rather than proteid deficiency. Moreover, that other factors than the quantity of food have to do with it is shown by the complaints of star patients whose food furnished more than twice as much proteid as Chittenden recommends and 2,398 calories.

Fourth, Crichton-Browne urges that "busy men have not time to go to bed and starve for two or three days when they have not appetite, nor can they devote a large portion of their lives to mastication." His argument is not very conclusive.

Fifth, he says, "There has not yet been time for any convincing proof of the utility or even safety of the reduced proteid diet." He thinks that ill effects may develop in late life which can be ascribed to such dietetic restriction. But all this is problematic. If we do not know that the restricted diet is useful or safe, neither do we know that it is harmful. Chittenden's experiments, which extended over six months and more, show that there was no immediate ill effect and that none developed during that time. Crichton-Browne says of Chittenden's dogs: "They led a placid and cloistered existence and so asceticism probably suited them. Not until a pack of foxhounds have got satisfactorily through a winter's work on Chittenden's reduced diet can his experiments be accepted as anything more than a curious physiologic feat."

Sixth, he points to the natural diet of the infant at the breast, where the child gets of proteid what would be equivalent for a man of 150 pounds, from 122 to 145 grams; more than twice the allowance made by Chittenden for man.

Lastly, he points to the good effects of forced feeding in tuberculosis and neurasthenia and after infections. He believes that there is no evidence of an accumulation of clinkers because of the heavy stoking.

This little book is well worth reading and considering. As stated, the book is polemical, and like all such it has the faults of a debate and it awakes contention in its readers. It is well, however, for physicians and laymen to halt and consider carefully the pros and cons of this subject.

LIFE'S DAY. By William Seaman Bainbridge, A.M., M.D. Cloth. Pp. 308. Price, \$1.35. New York: Frederick A. Stokes Co.

The fanciful title of this book suggests that it was intended for non-medical readers; and the foreword explains that it is based on a series of lectures delivered at Chautauqua. It appears to be designed especially to enlarge the mental horizon of those who have much leisure and little information; it treats sketchily the subjects of heredity, environment, edu-

cation, infancy, childhood, the "irresponsible age," adolescence, middle age and old age. A little biology, a little physiology, a little hygienic theory and precept, liberally sprinkled with quotations from poets and men of science, make up a volume which will be found, by those who like that kind of thing, to be just the kind of thing they like. Dr. Bainbridge has an agreeable style, and says that he is not a faddist or an overzealous enthusiast, but merely an earnest advocate of common sense and moderation in all things.

THE THEORY AND PRACTICE OF INFANT FEEDING. By Henry Dwight Chapin, A.M., M.D., Professor of Diseases of Children at the New York Post-Graduate Medical School and Hospital. Edition 3. Cloth. Pp. 350, with illustrations. Price, \$2.25. New York: William Wood & Co., 1909.

In this new edition of his book Dr. Chapin emphasizes as before the "biologic" aspect of infant-feeding with especial reference to the specificity of the milk of each mammal to its own young; devotes 100 very instructive pages to the subject of cow's milk, its composition, production, handling, examination, etc., and elaborates his views on the value and use of dextrinized (even standardized) gruels. The general recommendations about infant-feeding itself are in harmony with the views of the so-called "American school." The peculiar indifference of certain American writers on infant-feeding to what is being done abroad is nowhere exemplified better than here. The five years since the appearance of the last edition have been by far the most fruitful in this subject—the work of Budin and Heubner has been recognized, and that of Czerny and Keller and Finkelstein and others has revolutionized the whole subject in that time and has put it, for the first time, on a rational scientific basis. And yet in the 350 pages of this book no intimation is given of this truly epoch-making work. Except for the excellent chapters on cow's milk and for the originality of its ideas about the "biologic" aspect of infant-feeding and of the use of dextrinized gruels the book is disappointing so far as it relates to the present status of the science and art of infant-feeding.

The Public Service

Army Changes

Memorandum of changes of stations and duties of medical officers, U. S. Army, for the week ended May 29, 1909:

Bally, H. H., capt., ordered to accompany troops from Washington Barracks, D. C., to San Francisco, and then return to Fort Myer, Va.

Gostin, B. S., 1st Lieut., granted leave of absence for three months, when relieved from duty in the Philippines Division.

Waterhouse, S. M., major, granted leave of absence for four months, when relieved from duty in the Philippines Division.

Ireland, M. W., major, ordered to proceed to New York City and return, on business pertaining to the medical supply department.

Harris, J. R., capt., relieved from duty at Fort Worden, Wash., and ordered to Fort George Wright, Wash., for duty.

Hall, J. F., capt., granted leave of absence for four months, about Oct. 15, 1909.

Shillock, Paul, major, ordered to Hot Springs, Ark., for treatment at the Army and Navy General Hospital.

Vose, W. E., capt., granted leave of absence for two months, about August 20.

McCulloch, C. C., Jr., major, granted leave of absence for four months.

Shockey, M. A. W., major, granted leave of absence for one month, about June 3.

Morse, A. W., major, relieved from duty at Fort Leavenworth, Kan., and ordered to the Presidio of Monterey, Cal., for duty.

Keefe, F. R., major, relieved from duty at the Presidio of Monterey, Cal., and ordered to Fort Wadsworth, N. Y., for duty.

Navy Changes

Changes in the Medical Corps, U. S. Navy, for the week ended May 29, 1909:

Bogert, E. B., Jr., surgeon, detached from the Naval Academy and granted leave until Sept. 15, with permission to go abroad.

Ledbetter, R. E., surgeon, commissioned surgeon, with rank of lieutenant-commander, from Sept. 19, 1908.

Gill, J. E., P. A. surgeon, detached from the *Dubuque* and ordered home to wait orders.

Smith, C. W., asst.-surgeon, detached from the Naval Hospital, Norfolk, Va., and ordered to the *Dubuque*.

Rose, M. E., asst.-surgeon, ordered to the Naval Hospital, Norfolk, Va.

Fiske, C. H., surgeon, commissioned surgeon, with rank of lieutenant-commander, from Sept. 1, 1907.

Eutler, C. St. J., surgeon, commissioned surgeon, with rank of lieutenant-commander, from Oct. 11, 1908.

Cole, H. W., Jr., P. A. surgeon, commissioned P. A. surgeon, with rank of lieutenant, from Oct. 5, 1908.

Public Health and Marine-Hospital Service

List of changes of stations and duties of commissioned and other officers of the Public Health and Marine-Hospital Service for the seven days ended May 26, 1909:

Kerr, J. W., asst.-surgeon general, detailed to represent the service at the meetings of the American Association of Medical Milk Commissions, June 7, and the American Medical Association, June 8-11, 1909, in Atlantic City, N. J.

Wasdin, Eugene, surgeon, granted 1 month's leave of absence from May 22, 1909, on account of sickness.

Cobb, J. O., surgeon, granted 2 months' leave of absence from June 15, 1909.

Billings, W. C., P. A. surgeon, relieved from duty at the Revenue Cutter School of Instruction and directed to report to the commanding officer of the practice cutter *Itasca*.

Fox, Carroll, P. A. surgeon, granted 7 days' leave of absence from May 13, 1909.

Currie, Donald H., P. A. surgeon, detailed as director of the Leprosy Investigation Station at Molokai, T. H., to take effect June 1, 1909, vice acting asst.-surgeon Walter H. Brinckerhoff, resigned, to take effect May 31, 1909.

Holt, J. M., P. A. surgeon, granted 1 month's leave of absence from July 5, 1909.

Herring, R. A., asst.-surgeon, granted 1 month and 4 days' leave of absence from June 5, 1909.

Hamilton, H. J., acting asst.-surgeon, granted 9 days' leave of absence from May 8, 1909.

Hunter, Sam. B., acting asst.-surgeon, granted 4 days' leave of absence from May 18, 1909.

Nauty, Charles W., Jr., acting asst.-surgeon granted 14 days' leave of absence from June 11, 1909.

APPOINTMENT

Kellogg, Dr. W. H., appointed an acting asst.-surgeon for duty in the office of the U. S. consul at La Guayra, Venezuela.

BOARD CONVENED

Board of medical officers convened to meet at the Bureau May 18, 1909, for the purpose of making a physical examination of an officer of the Revenue-Cutter Service. Detail for the board: Asst.-Surgeon General W. J. Pettus, chairman; P. A. Surgeon, J. W. Trask, recorder.

Health Reports

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, Public Health and Marine-Hospital Service, during the week ended May 28, 1909:

SMALLPOX—UNITED STATES

California: Los Angeles, May 1-8, 1 case; Sacramento, May 8-15, 2 cases; San Francisco, May 1-8, 1 case; Stockton, April 1-30, 1 case.

Colorado: March 1-31, 81 cases.

Georgia: Macon, May 9-16, 2 cases.

Illinois: Danville, May 9-16, 10 cases; Galesburg, May 8-15, 1 case; Springfield, May 7-14, 1 case.

Indiana: Evansville, May 8-15, 1 case; Fort Wayne, May 1-8, 2 cases; South Bend, May 8-15, 1 case.

Iowa: Council Bluffs, May 9-16, 1 case; Davenport, May 2-9, 2 cases.

Kansas: Atchison, Feb. 27-April 17, 5 cases; Kansas City, May 8-15, 11 cases, 2 in vicinity; Wichita, May 8-15, 4 cases.

Kentucky: Lexington, May 8-15, 5 cases; Newport, 1 case; Paducah, May 1-15, 12 cases.

Louisiana: New Orleans, May 8-15, 6 cases.

Maine: Van Buren, May 8-15, 1 case.

Minnesota: Duluth, May 6-13, 9 cases.

Nebraska: Lincoln, April 1-30, 24 cases.

New Jersey: Perth Amboy, March 4-April 29, 30 cases.

North Carolina: Charlotte, May 7-14, 1 case.

Ohio: Cincinnati, May 7-14, 9 cases; Massillon, May 9-16, 1 case; Toledo, May 1-8, 1 case; Warren, 1 case.

Tennessee: Knoxville, May 8-15, 1 case.

Texas: Fort Wayne, April 1-30, 15 cases; San Antonio, May 1-8, 1 case; Waco, May 21, 4 cases, imported.

Virginia: Portsmouth, May 11-18, 4 cases.

Washington: Seattle, April 1-30, 4 cases.

West Virginia: Wheeling, May 8-15, 1 case.

Wisconsin: Milwaukee, May 1-15, 5 cases.

SMALLPOX—INSULAR

Philippine Islands: Manila, March 20-April 10, 35 cases, 1 death.

SMALLPOX—FOREIGN

Algeria: Bona, April 1-30, 23 cases, 13 deaths.

Argentina: Buenos Aires, Feb. 1-28, 2 deaths.

Brazil: Bahia, March 27-April 17, 21 cases, 6 deaths; Sao Paulo, March 15-21, 2 deaths.

Canada: Halifax, May 1-8, 5 cases; Vancouver, April 1-30 1 case.

Chile: Santiago, April 27, epidemic.

China: Amoy, April 3-10, present.

Egypt: Alexandria, March 1-31, 8 cases, 4 deaths.

France: Marseille, April 1-30, 3 deaths; Paris, April 18-May 1, 4 cases.

India: Bombay, April 13-20, 18 deaths; Calcutta, April 3-10, 197 deaths; Madras, March 27-16, 6 deaths; Rangoon, April 3-10, 11 deaths.

Indo-China: Saigon, March 27-April 3, 7 cases, 5 deaths.

Italy: General, April 25-May 2, 12 cases; Genoa, April 1-30, 3 cases; Naples, April 25-May 2, 20 cases, 1 death.

Java: Batavia, April 3-10, 5 cases, 1 death.

Mexico: Chihuahua, May 2-9, 1 death; Guadalajara, April 22-29, 2 deaths; Monterey, May 2-9, 8 cases; Puebla, May 10, present.

Portugal: Lisbon, May 1-8, 12 cases.

Russia: Moscow, April 17-24, 35 cases, 8 deaths; Odessa, April 17-24, 1 case, 2 deaths; Riga, May 1-8, 2 cases; Warsaw, Feb. 27-March 6, 4 deaths.

Spain: Barcelona, March 1-31, 30 cases, 18 deaths.

Spain: Barcelona, April 27-May 3, 9 deaths; Valencia, April 24-May 1, 6 cases.

Straits Settlements: Singapore, May 27-April 3, 1 death.

Tripoli: Tripoli, April 10-24, 80 cases, 16 deaths.

Turkey: Constantinople, April 18-25, 4 deaths; Smyrna, April 8-15, 1 death.

YELLOW FEVER

Brazil: Bahia, March 27, 2 cases, 9 deaths; Para, April 18-May 1, 10 cases, 10 deaths.

Ecuador: Guayaquil, April 3-17, 36 cases, 10 deaths.

CHOLERA—INSULAR

Philippine Islands: Provinces, March 20-April 10, 245 cases, 126 deaths.

CHOLERA—FOREIGN

India: Bombay, April 13-20, 44 deaths; Calcutta, April 3-10, 111 deaths; Rangoon, 6 deaths.

Russia: St. Petersburg, April 29-May 6, 12 cases, 4 deaths.

PLAGUE

China: Amoy, April 10, present.

Ecuador: Guayaquil, April 3-17, 30 cases, 9 deaths.

India: General, March 27-April 10, 5,722 cases, 4,684 deaths; Bombay, April 13-20, 382 deaths; Calcutta, April 3-10, 85 deaths; Rangoon, April 2, 18 deaths.

Indo-China: Saigon, March 27-April 3, 2 cases, 2 deaths.

Japan: Kyoto, April 17-24, 1 case, 1 death.

Medical Economics

THIS DEPARTMENT EMBODIES THE SUBJECTS OF ORGANIZATION, POSTGRADUATE WORK, CONTRACT PRACTICE, INSURANCE FEES, LEGISLATION, ETC.

The Doctor as a Vicarious Philanthropist

In a recent issue of the *British Medical Journal* appears an unusually interesting editorial under the above title. As the problem considered is one which also confronts the American physician, the conclusions of our British contemporary will doubtless be of interest. After stating that "the position in which medical men are placed when called on to attend urgent cases of labor or street accidents, with the certainty that in most cases they will receive no remuneration, is fast becoming intolerable," the editorial says that two cases have recently occurred which forcibly emphasize this fact.

In the first case, a physician was severely criticized by the public press for not attending a street accident when sent for, notwithstanding the fact that he was not a police surgeon, that he had been refused payment by the police authorities in other cases to which they had called him and that he had notified them that he would not in the future respond to their summons. In spite of these facts, the newspapers made severe comments regarding his refusal to respond to the call.

In the second case, a physician was called late at night to go to a labor case and asked that his fee be guaranteed before he respond. The physician denies that he refused to go, but says that after some discussion the husband deliberately turned away. Another doctor was summoned and on his arrival found that twins had been born, but that the mother had died from heart failure through exhaustion. The coroner in his verdict on the case reminded the jury that the impression that a doctor is a public servant and is required to go whenever called is incorrect, as a doctor is entitled to payment for his services or to the assurance that he will be paid. The jury, in returning its verdict, stated that death was due to heart failure arising from exhaustion from want of proper attention and added a rider to its verdict that it was "unwise for doctors to raise the question of fees."

Commenting on the verdict, the editorial says: "What the jury probably meant but hardly liked to say after the coroner's remarks, was that doctors ought to go to cases whenever summoned without question, and trust to chance payment afterward." The editor then proceeds to state that if in a particular case the question were simply whether a doctor, knowing that refusal to attend a case would involve suffering or danger which he might prevent, yet refused to go on the sole ground that his fee was uncertain, he would fairly be deemed guilty of inhumanity, and that every mem-

ber of the profession will agree that, in the words of the Poor Law Commission, "the physical condition of the patient should be the first consideration."

But this is only half the question. The primary responsibility for making proper provision for medical attendance in confinement cases rests on the patient or on her husband. If they fail in their duty, it then falls on the community as a whole. This principle is clearly acknowledged in the case of paupers, who are cared for not only along medical lines, but in every way at the expense of the state, even though their poverty be their own fault. This is carried to such an extent that the medical treatment given paupers is actually better than that given those members of the working classes who are just above the grade of paupers. The editor consequently concludes that the duty of providing proper medical attendance in cases of labor, accident, etc., falls on the individual or on the state, and that if the individual does not make adequate provision for such services the state should do so. In the case cited above both the individual and the state had failed to do their duty and the burden of assuming this responsibility without any guarantee of proper compensation was thrust on the physician as a representative of the medical profession, which is thus made to carry the burden which should be borne by the whole of society instead of being placed on a part.

After commenting on the situation in England, in which the midwives act makes satisfactory provision for the care of women unable to pay for medical services, the editor asks, "In this state of things, what must medical men do? If they refuse to attend these cases without guarantee of a fee they are called brutal and inhumane. If they do attend, they are voluntarily taking on themselves the burden which the local government board acknowledges ought to be borne by the community. They are doing state work without state pay and, as experience shows, if they will do it, they may go on doing it indefinitely."

Regarding accident cases, in some of the larger cities in England definite arrangements are made for payment on a fixed scale of fees to medical men called by the police to attend cases of accident, but in by far the greater number of towns there is no provision at all. "The authorities simply evade their responsibility by trusting that the humanitarian feeling of medical men will compel them to do the work for nothing. It is impossible that this condition of affairs should continue. Humanity will always claim sacrifice and will always get it from the medical profession. It is freely admitted that a man's responsibilities for helping others increases with his ability to help, but it can never be conducive to the welfare of the community that any one section of the community should be systematically exploited for the rest. Sydney Smith says that philanthropy in practice generally meant that Jones thought that Smith should do something for the relief of people in distress and this view is generally held by the public in respect to medical practitioners. It is high time that even coroners and their juries should realize that however convenient it may be to be charitable at another man's expense, the doctor can not live if he is to be regarded as a vicarious philanthropist."

These principles are of the greatest importance. Obviously the duty of caring for the injured and suffering members of the community devolves either on the individual or on the community at large. If the individual does not provide or is not able to provide proper medical attendance, then it is plainly the duty of the community to furnish it for him. The obligation to furnish such relief rests on the physician the same as on any other individual member of the community, but it should be met by the doctor in the payment of exactly the same amount of taxes that is paid by every other citizen of the same degree of material prosperity and not by a special tax levied on him as a professional man, in the shape of unremunerated and gratuitous professional service. It is impossible to avoid the conclusion that the physician is every year becoming more and more a state health officer and that the community has cheerfully and unthinkingly allowed the medical profession to do the char-

itable work which by right should devolve on the community itself. The appeal is being made constantly to the humanitarian instincts of the individual physician and seldom, we are glad to say, without response, but this does not palliate the economic injustice perpetrated by the community in unloading its plain charitable duty on the medical profession, simply because he has heretofore tacitly permitted it.

Marriages

WILLIAM FRANCIS LARKIN, M.D., to Miss Lenore Beck, both of Chicago, June 2.

ROBERT J. BEEBE, M.D., to Miss Ida Schultzy, both of West Branch, Mich., May 19.

ARNOLD C. KLEBS, M.D., to Mrs. Harriet K. Newell, both of Chicago, in Connecticut, May 22.

CHARLES W. VROOM, M.D., Whitten, Iowa, to Mrs. Anna Vroom of Athens, Pa., February 4.

WILLIAM BUTLER LEE, M.D., Nashville, to Miss Robbie Church, of Franklin, Tenn., May 12.

W. HORACE WITHERSPOON, M.D., Harrodsburg, Ky., to Miss Margaret Stubbs, of New Orleans, April 12.

DAVID JUDKINS DICKSON, M.D., to Mrs. Katharine Griswold Winchester, both of New York City, May 20.

SAMUEL PIERSON BRUSH, M.D., North Creek, N. Y., to Miss Frances Lela Morse, of Troy, N. Y., May 27.

ELBERT A. AINSWORTH, M.D., to Mrs. Susie S. Ash, both of West Union, Iowa, at New York City, May 8.

ALEXANDER C. WENTZ, M.D., to Miss Mary C. Kemper, both of Hanover, Pa., at Camden, N. J., Dec. 1, 1908.

WILLIAM EDWARD MOSELEY, JR., M.D., Baltimore, to Miss Sadie Beatrice Armistead of Cleveland, at Baltimore, May 22.

Deaths

Oscar Otis Burgess, M.D. College of Physicians and Surgeons, New York City, 1857; formerly president of the San Francisco Gynecological Society, the City and County Medical Society of San Francisco, the Medical Society of the State of California; vice-president of the first Pan-American Medical Congress; and city physician of Rochester, N. Y.; assistant surgeon and afterwards consulting surgeon to the Woman's Hospital, San Francisco; assistant surgeon to St. Luke's Hospital and the Children's Hospital; at one time a member of the State Board of Health; died at his home in San Francisco, May 20, from cerebral hemorrhage, aged 77.

Charles Burnham Porter, M.D. Harvard Medical School, Boston, 1865; and later demonstrator of anatomy and professor of clinical surgery in his alma mater; a member of the Massachusetts Medical Society; for many years surgeon, and later consulting surgeon to the Massachusetts General Hospital; surgeon of the Armory Square Hospital, Washington, D. C., during the Civil War; formerly vice-president of the American Surgical Association, and president of the Boylston Society of Harvard Medical School; died suddenly at his home in Boston, May 21, from cerebral hemorrhage, aged 69.

Oscar Nettleton Taylor, M.D. University of California, San Francisco, 1899; a member of the American Medical Association; instructor in diseases of the eye, ear, nose and throat in the University of California; and one of the best known athletes of the West; died in Lane Hospital, San Francisco, May 23, from meningitis due to operation he attempted to perform on himself for the removal of a nasal spur.

Reuben Parsons Thompson, M.D. Long Island College Hospital, 1886; formerly of Red Bank, N. J.; who was sentenced to imprisonment for eighteen years for malpractice in 1881 and served during his sentence as head nurse and assistant physician in the hospital ward; died at the state prison, Trenton, N. J., May 16, on the eve of pardon, from pulmonary hemorrhage.

Adele Stuart Hutchinson, M.D. Boston University School of Medicine, 1877; for many years a practitioner of Minneapolis, Minn.; and a member of the staff of the City Hospital; for six years a member of the State Medical Examining Board; and for several terms president of the Medical Woman's Club; died at her home in Andover, Mass., May 20, aged 62.

Samuel Fisler Stanger, M.D. Jefferson Medical College, Philadelphia, 1875; formerly of Harrisonville, N. J.; for ten years a member of the Board of Prison Inspectors; resident physician at the New Jersey State Prison, Trenton; died at his home in Trenton, May 21, from heart and kidney disease, aged 59.

Julius C. Mills, M.D. University of Pennsylvania; Philadelphia, 1869; a member of the Medical Society of the State of North Carolina; surgeon of the Thirteenth North Carolina Infantry, C. S. A. during the Civil War; died at his home in Reidsville, N. C., May 18, from cancer of the stomach.

William Allen King, M.D. Minnesota Hospital Medical College, Minneapolis, 1888; a member of the Washington State Medical Association; city health officer of Blaine, Wash., and medical inspector in the U. S. Immigration service; died at his home, May 15, from pneumonia, aged 61.

Nels Gustaf J. Dahlstedt, M.D. University of Minnesota, Minneapolis, 1889; health officer and postmaster of Port Wing, Wis., since 1902, and town clerk, justice of the peace and secretary of the school board since 1904; died at his home, April 20, from locomotor ataxia, aged 60.

Max Julius Gerdes, M.D. California Eclectic Medical College, Los Angeles, 1900; College of Physicians and Surgeons, San Francisco, 1905; in the government service in the Canal Zone and stationed at Lobasco; died at Ancon, April 7, 1908, from typhoid fever, aged 38.

Luther Elsworth Zech, M.D. University of Maryland, Baltimore, 1892; a member of the Medical Society of the State of Pennsylvania and of the borough school board; died suddenly at his home in York New Salem, Pa., from angina pectoris, May 22, aged 47.

Eugene LaFon Nelson, M.D. Rush Medical College, Chicago, 1864; assistant surgeon of the Eighth Illinois Volunteer Cavalry during the Civil War; died at his home in Springfield, Mo., April 20, from general debility, following cerebral hemorrhage, aged 69.

Benjamin Frank Lansdale, M.D. University of Maryland, Baltimore, 1866; representative in the Maryland legislature from Montgomery county, Md., in 1904; died at his home in Damascus, May 21, from cancer of the stomach, aged 64.

Harold Emory Jones, M.D. Kentucky School of Medicine, Louisville, 1900; M.R.C.S. Edinburgh, 1895; formerly physician to the Santa Fe System Hospital at Las Vegas, N. M.; died in New York City, May 12, from pneumonia, aged 36.

Wyllie C. Ogden, M.D. Bellevue Hospital Medical College, New York City, 1885; of Colorado Springs; a member of the Colorado State Medical Society; died at his old home in Fairmont, W. Va., May 12, from tuberculosis, aged 44.

Preston J. Edwards, M.D. Western Reserve University, Cleveland, 1892; of Montville, Ohio; a member of the Ohio State Medical Association; died in the Lakeside Hospital, Cleveland, May 16, from malignant disease, aged 58.

Alexander Harmon McLeod, M.D. University of Maryland, Baltimore, 1866; for many years an official of the Cincinnati, Hamilton and Dayton Railroad; died at his home in Wyoming, Cincinnati, May 11, from pneumonia, aged 73.

Allen Swan King, M.D. Tulane University, New Orleans, 1902; formerly of New Orleans; commander of the Berwick Division of the Louisiana Naval Brigade; was shot and killed in his office in Morgan City, La., May 19.

Walter E. Hall, M.D. Jefferson Medical College, Philadelphia, 1878; a member of the American Medical Association; a prominent citizen and philanthropist of Burlington, N. J., died at his home, May 22, aged 51.

Cyrus Pain Bryan, M.D. Jefferson Medical College, Philadelphia, 1855; of Savannah, W. Va.; died in the Greenbriar General Hospital, Ronceverte, W. Va., April 23, as the result of a fracture of the hip, aged 80.

Harry B. Clark, M.D. Chicago Homeopathic Medical College, 1903; a member of the Michigan State Medical Society; formerly of Manelona, Mich.; died at his home in Jackson, Mich., May 16, aged 29.

Romnald Arthur Girardin, M.D. Laval University, Montreal, 1898; of Menominee; a member of the Michigan State Medical Society; died in a sanitarium in Montreal, from locomotor ataxia, May 9, aged 40.

James L. Hedleston, M.D. Medical College of the State of South Carolina, Charleston, 1855; of Woodlawn, Ala.; a Confederate veteran; died at the home of his daughter in Woodlawn, May 19, aged 78.

Edward S. Harrison, M.D. Medical College of Georgia, Augusta, 1872; a member of the Medical Association of Georgia; died at his home in Thomson, May 20, from cerebral hemorrhage, aged 63.

John Murray Jordan, M.D. University of Pennsylvania, Philadelphia, 1883; for the last fifteen years a publisher of Philadelphia; died at his home in Germantown, May 19, from heart disease, aged 45.

David Maple Barkley, M.D. University of Louisville (Ky.) 1861; for 38 years a practitioner of Sturgis, Ky.; died at the home of his son in Parkland, Louisville, May 24, from senile debility, aged 75.

John David Shanor, M.D. Western Reserve University, Cleveland, 1881; a member of the American Medical Association; died at his home in Allegheny, Pa., from paralysis, May 18, aged 54.

Charles King, M.D. American University of Pennsylvania, Eclectic, Philadelphia, 1878; of Seattle, Wash.; died in the Pacific Hospital in that city, April 26, from erysipelas, aged 58.

Horace Bentley, M.D. Eclectic Medical Institute, Cincinnati, 1848; one of the founders of Woodbridge (Cal.) College; died at his home in Woodbridge, June 27, 1908, from paralysis, aged 80.

Frederick Wesley Park, M.D. Beaumont Hospital Medical College, St. Louis, 1890; a member of the Illinois State Medical Society; died at his home in Fieldon, Ill., May 7, aged 42.

James S. Carter (license, Tenn., 1889); of Selmer, Tenn.; a Confederate veteran; died in Memphis, May 14, two weeks after an operation for the removal of gallstones, aged 64.

J. N. Cowden, M.D. Cleveland University of Medicine and Surgery, 1894; died at his home in Lowellville, Ohio, Nov. 14, 1908, from cerebral hemorrhage, aged 68.

William C. A. Blauw, M.D. Bennett Medical College, Chicago, 1895; of Chicago; died in Cook County Hospital, Sept. 28, 1908, from chronic nephritis, aged 75.

James Leonard Burroughs, M.D. Maryland Medical College, Baltimore, 1903; died at his home in Louisville, Miss., April 19, from cerebral hemorrhage, aged 42.

Isaac Guss, M.D. Jefferson Medical College, Philadelphia, 1866; died at his home in Philipsburg, Pa., Feb. 14, 1908, from chronic bronchitis, aged 71.

John W. Cooper, M.D. Barnes Medical College, St. Louis, 1895; formerly of Terre Haute, Ind.; died at his home near Roff, Okla., recently, aged 35.

John William White, M.D. Eclectic Medical Institute, Cincinnati, 1898; died at his home in West Alexander, Pa., March 25, from tuberculosis, aged 35.

George H. Hightower, M.D. Georgia Eclectic Medical College, Atlanta, 1884; died at his home in Dalton, Ga., May 13, from acute gastritis, aged 55.

Henry Kehm, M.D. Jefferson Medical College, Philadelphia, 1871; died at his home in East Berlin, Pa., March 21, from locomotor ataxia, aged 64.

Andrew Sproule Martin, M.D. Trinity Medical College Toronto, 1898; formerly of Lipton, Sask.; died in Regina, Sask., May 1, aged 36.

John Wesley Colburn, M.D. Missouri Medical College, St. Louis, 1875; died at his home in Kansas City, Mo., May 4, from nephritis, aged 66.

Henry S. Jones, M.D. Louisville (Ky.) Medical College, 1862; died at his home in Corydon, Ky., May 22, from peritonitis, aged 74.

Samuel R. Bass, M.D. University of Louisville (Ky.), 1861; died at his home in Campbellsville, Ky., May 21, from rheumatism, aged 73.

Thomas Irven Elliott, M.D. Cleveland, 1854; died at his home in Sutton, W. Va., May 31, 1908, from organic heart disease, aged 81.

William Hughes, M.D. New York University, New York City, 1869; died at his home in Lima, Ind., May 13, aged 70.

George Warren Wild, M.D. Boston University, 1878; died at his home in Rochester, N. Y., May 24, aged 54.

John Foote, M.D. University of Buffalo, N. Y., 1851; died at his home in Kansas City, Mo., May 17, aged 81.

A. J. G. Hall, M.R.C.S. Edinburgh, Scotland, 1845; died at his home in Kimmundly, Ill., April 1, aged 90.

L. Young Hayes (license, Tenn., 1904) died at his home in Fayetteville, Tenn., May 18, aged 41.

Miscellany

PREMATURE BURIAL

Alleged Cases Usually Found to be Based on Hearsay and Presumptive Evidence

The subject of premature burial has long been a favorite theme for lovers of the gruesome and for those who find a delight in creating imaginative horrors on which to expend a perverted sense of sympathy. Like the vividly gory details to be found in antivivisectionist "literature," the testimony given by those whose hobby is "burial alive" is of the hearsay and presumptive order and invariably apocryphal. A case that would have furnished the basis for an elaborate "thriller" on the subject of premature burial, was discussed in the *Medical Press and Circular*, March 17, 1909.

While a grave was being filled, in an English village churchyard, sounds of rapping were heard which it was thought proceeded from the coffin. The lid of the coffin was immediately removed by the undertaker and a physician was summoned. The corpse, however, appeared exactly as when placed in the coffin, and there was not the slightest evidence that any movement had occurred. The coffin was replaced and as for the second time the grave was being refilled, rapping was again supposed to occur. As our British contemporary says: "Had the affair not been at once investigated, it would doubtless have added another to the bogus stories quoted in support of the gruesome assumption that live burial is of frequent occurrence."

We have investigated at different times some of the reports of premature burials or premature encosinments that crop up perennially in the press. The following appeared in a Boston publication, *Our Dumb Animals*, February, 1908:

PREMATURE BURIAL

Wichita, Kan.—John Clark, an inmate of the Soldiers' Home, in Dodge City is said to have been buried alive for two days. He had been ill with typhoid fever. The doctor in attendance pronounced him dead, and he was buried in the soldiers' cemetery with military honors.

Some of his comrades declared that they did not believe Clark was dead. One soldier, named Hazen, persisted that Clark had been buried alive, and demanded that his body be taken from the grave. The doctor was recalled and asked what he thought about the case.

After consultation it was decided to open the grave. When the coffin was opened it was seen that Clark's hands were not in their former position and there was moisture on the glass above his mouth. Stimulants and careful nursing turned the tide for Clark and death was robbed of its victim.

When Clark was finally restored to consciousness he said that he had been half conscious of all that had happened and knew that he had been buried alive.

He was buried on Wednesday and taken out on Friday.—*Boston Herald*

At the time this article appeared we looked into the matter and found the story an evident fake. A physician of Dodge City, in fact, writing to us about the report, said:

"I have made diligent inquiry and find that the story is entirely untrue. Nothing of this character has ever occurred at the Soldiers' Home at this place."

On October 21 of last year the following appeared in the *Chicago Tribune* and other papers:

WOMAN'S BURIAL ALIVE PREVENTED JUST IN TIME

Ellis, Kan., Oct. 20.—The timely intervention of a physician who was not satisfied with the appearance of the body to day prevented the burial alive of Mrs. Thomas Chapman, wife of one of the best known citizens of this part of Kansas.

Mrs. Chapman, who is 60 years of age, was supposed to have died suddenly from heart disease on Saturday last. The body was prepared for burial but was not embalmed. The funeral was to have taken place this afternoon.

A few minutes before the casket was to be sealed a physician requested permission to see the body. After confirming his suspicions, the woman was removed from the coffin and placed in bed. While her heart is weak, it is believed Mrs. Chapman will recover.

On corresponding with the physician referred to in the news item, we received the following reply:

"On Saturday, October 17, I was called to see Mrs. Thomas Chapman. Examination revealed no signs of life, and naturally I pronounced her dead. On Tuesday, October 20, I was asked to visit again the body, as some of the death signs were not plain. In company with _____ I returned and for the second time pronounced her dead. The funeral was delayed another twenty-four hours. There never were any signs of life in the body after she was first pronounced dead."

The following case illustrates a possible method of keeping up interest in the subject of premature burial. In the issue of *Our Dumb Animals* for February, 1909, this item appeared:

PREMATURE BURIAL

A prominent gentleman of Newport, R. I., sends us to day from the *Newport Herald* an article of deep interest on this subject, describing how Mrs. Christina Hart, of 1131 St. Louis Avenue, East St. Louis, was pronounced dead by her physicians and barely escaped being embalmed by the undertaker. She was entirely conscious during the whole trance of everything that was going on about her and of all that was said.

On making inquiries we found that no one of that name lived at the address given, and in following up the matter the editor of *Our Dumb Animals* was asked to give the date of the particular issue of the *Newport Herald* which contained the original account. It was then learned that though the article states that "A prominent gentleman . . . sends us to day," etc., the facts were that the same article had appeared in the same magazine *nine years previously*. Any cause which requires the dishing up as current matter news items that are admitted to have been in cold storage for at least nine years, must be in a bad way!

From practical considerations alone the probability of premature burial is so remote as to be negligible. We have but to bear in mind the fact that the amount of air in the modern air-tight coffin would support life for but a few brief minutes at most, to realize that the stories of resuscitation occurring as the coffin is being placed in the grave are the sheerest of fiction. The very general employment of methods of embalment also tends to make premature burial, if not impossible, at least highly improbable. Last, but not least, the most careless of physicians is not at all likely to pronounce a person dead without having assured himself of the fact. Yet we read in a pamphlet issued by a society for the prevention of premature burial the following intemperate statement:

If the present practice is to be continued, establish slot machines, where, by putting in a cent, a [death] certificate may be ground out. The certificate would be equally valuable and possess all the elements of intelligence and medical knowledge that the present certificates possess at a vast saving of salaries for medical examiners and medical certificates.

What grounds this society has for gratuitously insulting physicians by impugning their intelligence and medical knowledge and accusing them of incapacity or worse, it is impossible even to guess. If its statistics will bear no closer scrutiny than the few cases which we have investigated, the society probably believes in making up in invective what it lacks in testimony. Such methods are common in cases of organized hysteria. Quoting our British contemporary again: "The life of man is already surrounded by a sufficiency of trials and difficulties without adding gratuitous terrors to the list."

STEAMING THE BLOOD, A NEW CURE FOR PRURITENY

Berlin.—The Kaiser has given the highest medical post in Berlin . . . to Prof. A. — B — — —, . . . the inventor of two valuable surgical processes—the artificial steaming of the circulation of the blood as a cure for prurient abscesses, and the injection of anesthetics into the spinal marrow, which is used for rendering the lower part of the body unconscious.—*Los Angeles (Cal.) Examiner*.

Russian Researches in 'Metabolism.'—Of recent years the activity of Russian investigators in problems of animal nutrition and metabolism have been to a great measure overlooked. Dr. Francis G. Benedict of the Nutrition Laboratory of the Carnegie Institute of Washington, has recognized these Russian researches as among the best (*Science*, March 5, 1909.) For this reason and on account of the comparative inaccessibility of Russian literature to American scientists, he has made arrangements with Professor Lihachev, whereby all articles in Russian dealing with problems of metabolism are to be sent to the nutrition laboratory for translation into English. Manifolded copies of these translations will be deposited in the library of the laboratory. Dr. Benedict promises that titles and short abstracts of the articles will be published from time to time in some scientific journal. In their digest of metabolism experiments Atwater and Langworthy (*U. S. Dept. of Agric., Bull. 45, Office of Exper. Stations*) review the Russian literature up to that date. Among the more recent the following excellent articles have appeared in Russian: "Investigations of Gas and Heat Exchange in Fevers," "Production of Heat by Healthy Man in a Condition of Comparative Rest," "The Influence of Alcohol on the Heat and Gas Exchange in Man," and "Metabolism During Fasting." Of Pashutin's treatise on experimental pathology the entire section (some 800 pages) has been translated. Bound type-written copies are deposited in the Surgeon-General's library in Washington, the New York Public Library, and in the John Crerar Library of Chicago.

The Mechanical and Physiologic Effects of an Excessive Dilatation and Elongation of the Colon. Dr. A. Campbell Geddes (*Jour. Anat. and Physiol.*, 1909, *liiii*, 182) describes with several good illustrations the effects of marked dilatation and elongation of the cecum, ascending colon and transverse colon on the abdominal and thoracic viscera and on the organism in general. Reference is made also to the effects of a similar condition in the transverse and descending parts of the colon, described by Professor Howden. The observations which were made in the anatomic laboratory of the University of Edinburgh show instances of remarkable dilatation. A maximum diameter of 220 mm. for the cecum, 280 mm. for the ascending colon and 170 mm. for the transverse colon, with a combined increase in length of over 100 per cent for these three portions of the intestine are recorded. From his dissections, Dr. Geddes concludes there may be attributed to an excessive dilatation and elongation of the cecum, ascending and transverse parts of the colon the following effects: displacement of the heart to the left, backward displacement of the left lung, a shortening of the right lung, a translocation and rotation of the liver, direct distortion of the stomach, indirect distortion and downward displacement of the right kidney, a partial functional obliteration of the abdominal venous system (inferior vena cava and abdominal veins), the establishment indirectly of a condition of general extra-abdominal congestion and indirectly a hypertrophy of the heart.

The Temperature in the Human Stomach.—Dodo Raucken and R. Tigerstedt, in *Skandin. Arch. f. Physiol.*, *xxi*, 80, record the temperature of the stomach, taken every four minutes for eighteen hours in the case of a woman of 62 years, with a stomach fistula. At the same time the temperature of the rectum was taken. Each series of temperature readings is graphically plotted in curves showing hourly and half hourly averages. The stomach and rectal temperatures ran in general parallel, the former showing an average of 0.09 C. higher than

the latter. Only on taking food of a lower temperature than that of the body did the temperature of the stomach sink below that of the rectum. The close similarity of the two curves and the fact that the maximal difference between them occurred twelve hours after taking food, are taken to indicate that during stomach digestion no perceptible increase in the temperature of the organ is experienced. It is probable that the surrounding viscera, especially the liver, may account for a higher temperature in the stomach than in the rectum.

Baths of Tiberias.—According to Consul General G. Bie Ravndal of Beirut (*Monthly Consular and Trade Reports*, March, 1909), there is good opportunity for development, under American or European management, of a health resort near the hot springs of Tiberias in Palestine, which may rival Carlsbad. These springs have been noted for their healing properties since Roman times. The temperature is about 143 F. and the waters contain sulphur, magnesium chlorid and iron. Baths have been provided by the Turkish government, but the accommodations are inferior and lack cleanliness. In Galilee the climate is delightful in the spring and the season lasts from February to May. A resort offering such baths and such historic associations would seem to have a bright future.

Provision for Public Care of Epileptics.—An instructive little booklet on epilepsy entitled "Public Care and Treatment for the Epileptic" has been prepared by Dr. J. F. Munson, secretary-treasurer of the National Association for the Study of Epilepsy, and Mr. William C. Graves, executive secretary of the Illinois State Board of Commissioners in Charity. It is designed for the layman and gives the reasons for public care of epileptics, the superiority of colony to hospital care and a list of the states which have already provided institutions of this character. Unfortunately, the list is not a long one, only nine states being named as having established separate institutions for epileptics. The booklet ought to have a strong influence in stimulating legislators to make adequate provision for these people, who are unfortunate and disabled through no fault of their own.

Typhoid Fever and Venereal Disease in the British Army in India.—Among the points brought out in the Annual Report of the Sanitary Commissioner with the Government of India for 1907, one or two in connection with typhoid fever are of general as well as of local interest. A very conclusive instance of the bacillus carrier is reported as follows:

"During August, 1907, five cases of enteric fever occurred in the detachment of the Bedfordshire regiment stationed at Kasauli. All the patients contracted the disease about the same time. They lived in different rooms and the only conditions common to all were the food supply and the latrine accommodation. The source of infection remained undiscovered until a bacteriologic examination of the excreta of all the cooks and 'contacts' in the detachment (42 in all) was made. The investigation proved that a cook of the detachment, who was apparently in perfect health, was excreting the typhoid bacillus in enormous numbers in his feces. The man was isolated and no further case occurred in the detachment. It was probable that he had been a typhoid bacillus-carrier for nearly ten years."

The committee of investigation also found that soldiers employed as nurses to typhoid patients may become bacillus-carriers without themselves being attacked by the disease. This was found to be the case with regard to three out of five nursing orderlies whose histories are recorded in the report.

Another observation which the report thinks has not had sufficient importance attached to it in general, except perhaps in India, is the danger of infection by contact during the very early stages of typhoid fever. In the tendency which there is at the present time to attribute the origin of so many cases of typhoid to the agency of convalescents and chronic bacillus carriers, there is perhaps a danger that the importance of the infectiousness of patients in the early stages of the disease may be overlooked.

It is noteworthy that the hospital admissions for alcoholism and venereal diseases in the British troops show a considerable fall over 1906. Among the contributory causes of this fall are the official efforts to occupy the spare time of the men in healthy pastimes, to make the regimental institutes attractive and comfortable, as well as a better education and a higher moral tone among soldiers generally. The decline extends also through the native troops. The indication of the decline in syphilis among European troops is shown by the "syphilis register," which contains the names of all men who come under treatment for syphilis for the first time. It was started in 1904, and 2,947 men were entered. In 1905 there were 1,470; in 1906 there were 936; and in 1907 only 797 entered. Every man whose name is on this register has to attend hospital once a week for observation and treatment during a period of two years, and the continuous improvement and results of treatment are shown by the steady decrease in the proportion of cases requiring readmission to hospital while under observation.

State Dependency and Criminality.—In 1908 a commission was appointed in New Jersey to investigate the causes of dependency and criminality. That commission, finding it impossible to cover the entire field in the short time allotted, has recently issued a partial report, for a copy of which we are indebted to Dr. Charles A. Rosenwasser, chairman. The report contains some interesting suggestions, which, though naturally directed to the State of New Jersey, nevertheless bear on problems that exist in most of the states, and are therefore worthy of consideration. The commission recommends the abolition of all state boards of managers and the substitution in their place of a commissioner of charities, who should be a specialist in all phases of work in the institutions of the state, and who should work subject to a board of charities and corrections. The report strongly recommends the unification, with centralization of authority, control, and management, of all state institutions. The system of detaining in the county jail in close contact with criminals those who are merely accused or desired as witnesses, and also juvenile and first offenders, is properly and strongly condemned. The abolition of the Sunday restriction on sports and games, a relic of "harsh laws made to fit other times, other peoples, and other conditions," is urged. The disposition of the insane receives careful consideration. A law is recommended to provide for the voluntary commitment of the insane, on the ground that such a law would render it possible to get patients under treatment in the early stages of insanity. There can be little doubt that, as in other diseases, so in insanity, early treatment leads to more cures. Owing to the conflicts that occur between portions of laws enacted at different times and under different circumstances, the commission recommends a repeal of all the laws dealing with insanity from 1846 to date, and the enactment of one comprehensive law to embrace all features necessary to cover requirements in the commitment, detention and discharge of the insane. Other points of general interest considered in the report are the recommendation of a hospital for inebriates to replace the barbarous system of punishment, restriction of marriage in the case of persons physically or otherwise unfitted to marry, the education of the public in matters of health, especially sexual hygiene, the prevention of ophthalmia neonatorum, and records of the sale of dangerous weapons. A mode of equalizing the distribution of insane patients according to available accommodation in the various hospitals, is suggested. The report further discusses women's reformatories, state homes for boys, the harmfulness of dead letter laws, the medical examination of prisoners (in the absence of which tuberculosis and other transmissible diseases may be spread), the separation of juvenile prisoners from adults and of male from female inmates in institutions. The report is one which shows good work and in the main inculcates sound principles.

The New Jersey Campaign Against Mosquitoes.—Prof John B. Smith, in his report to the governor on the work carried on under the former's direction, for the two years ending

with the summer of 1908, discusses the problems encountered by the state of New Jersey in its attempt to exterminate the mosquito. It is his opinion that this pest can be practically exterminated if the campaign is continued. Drainage of 20,292 acres of salt marsh has been accomplished by 2,723,974 feet of ditching at an actual cost of \$44,058. Considerable money was also expended by municipalities throughout the state, which cooperated with the mosquito commission in its crusade. Breeding places were eliminated. Boods of wigglers in pools were destroyed with oil. In those localities where the marshes were well drained during or before 1907, the migrating marsh mosquitoes were practically absent during 1908. It has been found that the eggs of the species that are typical of these salt marshes are capable of hatching at least three years after a marsh is drained. Particular attention was also directed to water barrels, catch-basins, cisterns, etc., in the larger towns. It is hoped that the legislature will extend the appropriation so that the crusade may be continued.

Economic Aspects of Animal Tuberculosis.—When a disease can be shown to inflict commercial loss its control or eradication is generally assured. According to a recent report of the Bureau of Animal Industry the meat inspection figures show that tuberculosis among live stock is increasing steadily and that nearly 1 per cent of cattle and over 2 per cent. of hogs slaughtered are tuberculous, which is surely an alarming condition. Experiments indicate that hogs can be infected through the ingestion of feces and milk from tuberculous cows. There is, therefore, no doubt that the prevalence of the disease in hogs could be greatly reduced simply by eradicating it from cattle. The prevalence of the disease is further shown by results of the testing of dairy herds in Washington, D C, and elsewhere. Tuberculin tests made in various states warrant the estimate that in the country at large at least 10 per cent of the cows in dairy herds are tuberculous. The results of tests showed that in some of the pure-bred herds nearly 50 per cent. of the animals were diseased and in consequence sales were lost. This loss is inducing some buyers of breeding cattle to insist on having pure bred animals tested before placing them in their herds. When this practice becomes general the breeder of strictly healthy cattle will be much sought after. The avoidance of loss due to the condemnation of a valuable animal on account of disease would compensate for the necessary expense of inspection and other means of prevention. Sooner or later the man who raises tuberculous animals must suffer the loss, unless the loss is paid for out of public funds; and when the loss is placed on the producer we may then know that the end of the disease is in sight.

Medical Education and State Boards of Registration

COMING EXAMINATIONS

DELAWARE	Dover and Wilmington, June 15-17.	Sec., Dr Henry W Buggs, Wilmington
FLORIDA	ELECTIC DeFuniak Springs, June 10	Sec., Dr. Hiram J Hampton, Tampa
ILLINOIS	Coliseum Annex, Chicago, June 16-18	Sec., Dr. J. A. Egan, Springfield
IOWA	Des Moines, June 22-24; Iowa City, June 8-10.	Sec., Dr. Louis A Thomas, Des Moines
KANSAS	Kansas City, June 10	Sec., Dr. R. A. Light, Chanute
MARYLAND	Baltimore, June 15-18	Sec., Dr. J. M. Scott, Hagerstown.
	Homeopathic Baltimore, June 15-17	Sec., Dr. Joseph S. Garrison, 848 W. North Ave.
MICHIGAN	Ann Arbor, June 8	Sec., Dr. B. D. Harrison, 504 Washington Arcade, Detroit
MINNESOTA	Minneapolis, June 15	Sec., Dr. W. S. Fulletton, St Paul
NEW JERSEY	State House, Trenton, June 15-16	Sec., Dr. J. W. Bennett, Long Branch
NEW YORK	Albany, June 22-25	Chief of Examinations Division, Dr. Charles F. Wheelock, Albany
NORTH CAROLINA	Asheville, June 9	Sec., Dr. B. K. Hays, Oxford
OHIO	Columbus, June 8-10.	Sec., Dr. George H. Matson, State House, Columbus
PENNSYLVANIA	Philadelphia and Pittsburg, June 22-25	Sec., Mr. Nathan C. Schaeffer, Harrisburg.

SOUTH CAROLINA: Columbia, June 8-10. Sec., Dr. H. H. Wyman, Alken.
TEXAS: Cleburne, June 22-24. Sec., Dr. M. E. Daniel, Honey Grove.
VIRGINIA: Richmond, June 22-25. Sec., Dr. R. S. Martin, Stuart.
WYOMING: Laramie, June 23-25. Sec., Dr. S. B. Miller.

Nebraska College of Medicine Closes Voluntarily

Recognizing the rapidly increasing demands of medical education and the impossibility of its meeting these demands with the means at its disposal, the Nebraska College of Medicine has voluntarily closed its doors. This action was taken by the faculty at a meeting held May 19th. In an open letter to the president of the Nebraska Wesleyan University, with which the medical school was affiliated, Dr. J. F. Stevens, dean of the medical college, sets forth the reasons leading to the action taken. After giving a brief history of the opening and progress of the medical school, Dr. Stevens continues:

"We would respectfully call your attention to the fact that educators and physicians throughout the United States, recognizing the inferiority, on the whole, of the American medical school, as compared with those of Europe, have determined to raise the standard of medical education to such a point that our colleges will command the respect of the world. While academic training and opportunity have grown into magnificent and commanding proportions, the professional schools, with the exception of a small minority, have remained essentially elementary or even worse. The spirit of progress has at last become supreme and on all sides may be seen the work of destruction, re-organization, and rebuilding. The American Medical Association is doing a splendid work in securing and digesting statistics, and reflecting the strengths and deficiencies of our institutions. The Carnegie Foundation, in a different manner, lends its words of wisdom, and a multitude of smaller bodies and societies, including state examining boards, are working together with hardly a discordant note, for the same purpose. Standards of entrance requirements have been raised to such a point that one full year's work in an accepted college or university is required for matriculation. Soon it will be two years, and later a bachelor's degree will, without doubt, be the *sine qua non*. Small colleges that have found it impossible to stand the strain of such requirements have been forced either to step from the field altogether, or to merge with some other school. In several states nearly, or quite all, of the small schools have been blended with the state institution. At the same time the requirement is going forth that schools shall have at their disposal a dispensary and hospitals sufficiently patronized to permit of a very wide study of disease. These requirements can not be met in a small city. Again, with the rapid advancement in medicine has come the need of costly laboratories, under the direction of highly cultured men. Subjects, too, that once belonged to the 'mere mention' hour in the course of study, have developed into great fields with divisions and subdivisions, each demanding a special training for its comprehension and most certainly for its proper teaching. None of these requirements insisted on by educators and the medical profession generally is in excess of what it should be, and this institution is in full harmony with that view.

We fully realize that to maintain our standing and dignity as medical teachers, in the continuance of our college, it will be necessary to add to our working force a goodly number of trained instructors. This we can not do, and because of this, and for the reasons easily deduced from the above discussion, it has been decided best for our institution to voluntarily close our doors, in the interest of higher medical education."

The action taken by the faculty of this college is but another evidence that medical educators themselves realize the desirability that medical teaching in America be improved until it is at least on the same high plane held in other leading countries, and that they are willing to make great sacrifices, if need be, to attain that end. It is this spirit so frequently manifested by our medical educators, which is an inspiration to those working for better standards and which is sure to bring results.

AMERICAN CONFEDERATION OF RECIPROCATING, EXAMINING AND LICENSING MEDICAL BOARDS

Annual Meeting, held at Louisville, Ky., May 12, 1909

The annual meeting of the American Confederation of Reciprocating, Examining and Licensing Medical Boards was held at Louisville, Ky., May 12, under the presidency of Dr.

W. A. Spurgeon of Muncie, Ind., who is president of the Indiana State Board of Medical Registration and Examination, the secretary-treasurer being Dr. B. D. Harrison, 504 Washington Arcade, Detroit, who is secretary of the Michigan State Board of Registration in Medicine. While the attendance was not so large as usual, owing to the fact that at this season medical colleges are holding or preparing to hold examinations, and medical boards are either conducting examinations or preparing to do so, a comparatively large number of state boards and medical colleges were represented. The local profession of Louisville was largely represented at the meeting, and also at the luncheon given to the delegates by Dean Evans of the Medical Department of the University of Louisville, at the Pendennis Club.

Dr. JOSEPH M. MATHEWS, president of the Kentucky State Board of Health, gave an interesting address on "Preliminary Requirements," and advocated conservatism in medical boards adopting higher standards, suggesting that the present standard should be absolutely obtained prior to any such advancement.

The presidential address was delivered by Dr. Spurgeon of Indiana and the secretary's report by Dr. Harrison of Michigan. The latter showed 827 licenses reported endorsed by the several reciprocating states in 1908, with eight states failing to report. Additional states reciprocating are, Texas, Oklahoma, Louisiana and New Hampshire. Information was also received by the secretary from the Board of Medical Examiners of Oregon, to the effect that this board would enter the reciprocating field in a short time, and that Washington and Idaho were also seriously considering medical reciprocity in the near future.

Article II of the constitution of the confederation was amended. It formerly read:

The object of this confederation shall be to establish reciprocal relations between the medical examining and licensing boards of the states, territories, districts and provinces of the United States; the purpose of which being that thoroughly worthy and well qualified physicians and surgeons who have been legally authorized to practice under the laws of one of said states, territories, districts or provinces, may be given legal authority and be admitted to practice in any state, territory, district or province represented in this confederation without a repetition of the tests of qualification to which such practitioner has submitted.

The amendment added the following:

"This confederation shall also adopt, from time to time, suggestive standards of preliminary and medical education. It shall also suggest methods of making practical the reciprocal endorsement of licenses."

Detail of Academic (Secondary) Work and Examination

The following detail of academic value of a high school diploma was adopted:

REQUIRED GROUP			
MINIMUM 40 COUNTS. (TOTAL OF 60 COUNTS.)			
	Credits Accepted.		
	Minimum	Maximum	
	Counts.	Counts.	
English	10	15	
Mathematics	10	20	
Latin	10	20	
Physics	5	5	
History	5	15	
Totals	40	75	
ELECTIVE GROUP			
MAXIMUM 20 COUNTS			
Greek	8	10	
French	8	10	
Spanish	8	10	
German	4	5	
Chemistry	2	5	
Botany	2	5	
Zoology	4	5	
Biology (see Note 3)	2	5	
Hygiene (see Note 3)	4	5	
(see Note 3)	2	5	
Note 3)	2	5	
Solid Geometry	3	5	
Physical Geography	3	5	
Drawing	4	5	
Astronomy	4	5	
Geology	1	5	
Total elective		37	

INSTRUCTIONS

1. As used in this table, a count is the measure of the work successfully completed in a secondary or high school pursued an entire

school year of 36 weeks in one weekly recitation period of not less than forty-five minutes.

2. The required group, 40 counts, must be presented by all applicants. Sufficient counts to make a total of 60 counts required may be selected from the elective group. The credit which will be accepted in the several studies is shown by the printed figures.

3. English literature of the elective group may not be counted unless a year has been given to that subject in addition to the required ten counts in English, and trigonometry may not be counted unless it is in addition to the required ten counts in mathematics.

4. Civics is not accepted as a subject, but may be counted as a part of American history.

5. Biology is the equivalent of botany and zoology, and it can be given no credit if an applicant is credited with botany or zoology.

6. The scope of the course is recorded under minimum standard of preliminary education.

The scope of such diploma was passed at the 1908 meeting. The committee having in charge the medical curriculum was continued and instructed to report at the next meeting.

The officers of the previous year were re-elected.

Arizona April Report

Dr. Aniel Martin, secretary of the Arizona Board of Medical Examiners, reports the written examination held at Phoenix, April 5-6, 1909. The number of subjects examined in was 9; total number of questions asked, 90; percentage required to pass, 75. The total number of candidates examined was 7, of whom 5 passed and 2 failed. The following colleges were represented:

College	PASSED	Year Grad.	Per Cent.
Northwestern University Medical School.....	(1903)	83.	
College of Physicians and Surgeons, Baltimore....	(1885)	78.2	
Medical College of Ohio.....	(1883)	75.6	
Western Reserve University.....	(1903)	86.3	
Jefferson Medical College.....	(1883)	81.2	

College	FAILED	Year Grad.	Per Cent.
Jefferson Medical College.....	(1885)	72.9	
Chattanooga Medical College.....	(1908)	72.5	

California April Report

Dr. Charles L. Tisdale, secretary of the Board of Medical Examiners of the State of California, reports the written examination held at San Francisco, April 6-8, 1909. The number of subjects examined in was 10; total number of questions asked, 100; percentage required to pass, 75. The total number of candidates examined was 67, of whom 44 passed and 23 failed. The following colleges were represented:

College	PASSED	Year Grad.	Per Cent.
College of Physicians and Surgeons, San Francisco, (1902)	75.2;		
(1906) 75.7, 76.6, 78.2, 80.5; (1907) 75, 76.2; (1908) 81.7, 82.1.			
University of California.....	(1908) 78.6, 79.9, 80.8, 89.1		
College of Physicians and Surgeons, Los Angeles.....	(1908) 75.		
University of Southern California, (1904) 75; (1906) 80.5; (1907) 75, 80.7; (1908) 75, 78.5.			
Hahnemann Medical College of the Pacific.....	(1908) 76.5		
California Medical College, Eclectic.....	(1906) 78.		
Cooper Medical College.....	(1905) 76; (1907) 79; (1908) 75.		
Yale Medical School.....	(1904) 86.4		
Dunham Medical College.....	(1902) 75.		
Northwestern University Medical School.....	(1899) 77.		
Rush Medical College.....	(1909) 90.9		
Medical College of Indiana.....	(1898) 81.3		
University of Iowa.....	(1892) 82.1		
Kentucky School of Medicine.....	(1893) 85.8		
Tulane University of Louisiana.....	(1908) 75.1		
Harvard Medical School.....	(1899) 83.5; (1907) 81.4		
University of Minnesota.....	(1896) 82.4		
St. Louis College of Physicians and Surgeons.....	(1908) 75.6		
Washington University.....	(1907) 87.4		
Marion Sims College of Medicine.....	(1898) 80.3		
Columbia University, College of Phys. and Surg.	(1907) 83.6		
Woman's Medical College of Pennsylvania.....	(1908) 84.2		
University of Vermont.....	(1900) 78; (1907) 75.		
University of Toronto, Ontario.....	(1906) 87.		

College	FAILED	Year Grad.	Per Cent.
University of Southern California.....	(1908) 72.4		
Hahnemann Medical College of the Pacific.....	(1908) 72.3		
College of Physicians and Surgeons, San Francisco, (1906) 45.5, 72.3, (1907) 70, 72.1.			
College of Physicians and Surgeons, Los Angeles.....	(1908) 28.52.		
Hahnemann Medical College and Hospital, Chicago, (1886) 75.8* (1898) 70.5.

University of Oregon.....	(1908)	73.8
Jefferson Medical College.....	(1894) 66.6; (1895) 56.2	
University of Vermont.....	(1907)	73.4

* Five per cent. added for each ten years of practice.

Wisconsin April Report

Dr. J. V. Stevens, secretary of the Wisconsin Board of Medical Examiners, reports the written examination held at Madison, April 13, 1909. The number of subjects examined in was 21; total number of questions asked, 100; percentage required to pass, 75. The total number of candidates examined was 3, all of whom passed. Twenty-three reciprocal licenses were issued at this examination. The following colleges were represented:

College	PASSED	Year Grad.	Per Cent.
College of Physicians and Surgeons, Chicago.....	(1902)	79, 81.	
Milwaukee Medical College.....	(1904)	79.	

LICENSED THROUGH RECIPROCITY

College	Year Grad.	Reciprocity with
Denver and Gross College of Medicine.....	(1903)	Iowa

Maine March Report

Dr. Frank W. Searle, secretary of the Maine Board of Registration of Medicine, reports the written examination

held at Portland, March 9-10, 1909. The number of subjects examined in was 10; total number of questions asked, 95; percentage required to pass, 75. The total number of candidates examined was 12, of whom 7 passed and 5 failed. Six applicants were granted reciprocal licenses. The following colleges were represented:

College	PASSED	Year Grad.	Per Cent.
Georgetown University, Washington.....	(1908)	84.7	
Medical School of Maine.....	(1892) 89.5; (1908)	75.9	
Tufts College Medical School.....	(1907)	87.4, 82.8	
College of Physicians and Surgeons, Boston.....	(1908)	83, 86.	

College	Year Grad.	Per Cent.
Medical School of Maine.....	(1908)	78.7
Baltimore Medical College.....	(1905) 73.4; (1906)	68.9
Coll. of Phys. and Surg., Boston....	(1901) 73.3; (1908)	67.6

LICENSED THROUGH RECIPROCITY

College	Year Grad.	Reciprocity with
Medical School of Maine.....	(1888)	New Hamp.
Baltimore University.....	(1898)	New Hamp.
Johns Hopkins Medical School.....	(1904)	Dist. Colum.
Dartmouth Medical School.....	(1904)	Vermont
New York Homeopathic College and Hospital.....	(1899)	Michigan
University of Vermont.....	(1907)	Vermont

Massachusetts March Report

Dr. Edwin B. Harvey, secretary of the Board of Registration in Medicine, reports the written and practical examination held at Boston, March 9-11, 1909. The number of subjects examined in was 13; total number of questions asked, 70; percentage required to pass, 75. The total number of candidates examined was 62, of whom 33 passed, including 1 non-graduate and 25 failed, including 8 non-graduates. The following colleges were represented:

College	PASSED	Year Grad.	Per Cent.
Hahnemann Medical Coll. and Hospital, Chicago.....	(1908)	77.2, 79.6	
College of Physicians and Surgeons, Baltimore.....	(1908)	79.2	
Baltimore Medical College.....	(1905) 79.3; (1908)	75.8	
Boston University.....	(1900) 76.2; (1906) 75.8; (1908)	75.9	
Tufts College Medical School.....	(1907) 75.3, 79.2; (1908)	75, 75.5, 76.3, 77.7, 81.7.	
Harvard Medical School.....	(1906) 75; (1907) 75.1, 75.2, 77.2, 79, 81.7; (1908) 80.5, 80.8.		
Columbia University, College of Phys. and Surg.....	(1893)	75.5	
Medico-Chirurgical College, Philadelphia.....	(1908)	77.5	
University of Pennsylvania.....	(1888) 77.6; (1906)	78.	
Jefferson Medical College.....	(1904)	78.5

University of Vermont.....	(1908)	89.	
University of Virginia.....	(1907)	89.	
Tennessee Medical College.....	(1908)	91.	

	FAILED	Year Grad.	Per Cent.
Tennessee Medical College.....	(1907)		78.

Wyoming February Report

Dr. S. B. Miller, secretary of the Wyoming Board of Medical Examiners, reports the written examination held at Cheyenne, Feb. 10-12, 1909. The number of subjects examined in was 10; total number of questions asked, 100; percentage required to pass, 75. Only one candidate, a graduate of Starling Medical College, 1898, appeared for examination, who passed with a percentage of 75.9.

AMERICAN THERAPEUTIC SOCIETY

Tenth Annual Meeting, held at New Haven, Conn., May 7-8, 1909
(Concluded from page 1782)

The Present Knowledge of the Action of Cathartic Drugs

DR. F. P. UNDERHILL, Yale University: Cathartic drugs act on the alimentary tract in a variety of ways, involving physical, chemical and physiologic activities. With the saline cathartics the essential factor is the production of an intestinal secretion by nerve stimulation, with simultaneous inhibition of absorption. Peristalsis is secondary. Most of the vegetable cathartics are peculiar in that they will produce their characteristic effects by whatever channel introduced, although certain untoward results may follow from subcutaneous injection. It is possible that the proposed derivatives of phenolphthalein will obviate this difficulty. Unlike the saline cathartics, the presence in the blood of vegetable purgatives appears to be the essential factor in bringing about purgation. The principal effect of this class is the production by local irritation of a very active peristalsis which hurries the intestinal contents along the bowel. From recent observations, it has been learned that different drugs may act on entirely different portions of the alimentary canal. Thus, the purgative oils, according to their condition (presence or absence of decomposition products) may influence the movements of the stomach and intestine or the intestine alone, while a drug like senna shows no action until the large intestine is reached.

SYMPOSIUM ON DIET

Chronic Constipation Clinically Considered

DR. L. M. GOMPERTZ, New Haven, Conn: In my studies I have been especially interested in experimenting with agar-agar, and its systematic use as a part of the patient's daily diet has been attended with good results in a number of instances.

The Relation of the Food Stuffs to Alimentary Functions

DR. LAFAYETTE B. MENDEL, Yale University: In place of the usual discussion of the effect of the digestive processes on foods, I take up the relations from a somewhat reversed viewpoint, namely, the influence of the foods on various alimentary functions, believing that such influences are worthy of consideration for their possible therapeutic significance. In connection with the modern theory of hormones, or chemical excitants, we have certain facts bearing on the importance of such agents in exciting secretory functions and regulating glandular activities. Thus, gastrin, a gastric secretagogue, is formed by the action of food substances like meat extract, dextrin, etc., and the clinician can provoke the flow of gastric juice by the appropriate selection of ingested foods, and re-

press it likewise (as by the use of fats) in dietetic as well as nervous ways. The effects which follow stimulation or inhibition of secretory glands along the digestive canal, and the interrelation of such activities, have now been studied. So, also, the secondary consequences of variations in secretory activity which are induced by dietetic factors. Examples of such are found in the relation of the gastric sphincters to acid contents in the stomach, intestinal putrefaction, and other similar phenomena. The possibilities of dietotherapy should be carefully considered, in distinction from that type of feeding which is guided by chance or ruled by tradition.

Diet as a Prophylactic and Therapeutic Agent

This paper, by DR. H. W. WILEY, Washington, D. C., was read by Dr. F. P. Morgan:

A perfectly healthy, well nourished organ becomes infected with any disease germ with great difficulty; in other words, it is self-protective. Hence, it is evident that the food, or diet, must play a most important part in the prevention of disease. It follows, necessarily, that the debasement of the diet, the addition of injurious substances thereto, or abstraction of valuable ingredients therefrom, must diminish the power of that diet to maintain the body in a state of hygienic equilibrium. All the constituents of the normal food of man have a useful function, and the sum of nutrition is the normal ingestion of the whole of these ingredients in their proper proportions. The first requisite we should make for foods for invalids is that they should be pure, and the next most important thing is to find a pure food which the invalid can digest. In the progress of medical education the near future, in my opinion, will see the professorship of dietetics in a medical school advanced to the same rank as that of medicine, and, further than this, I believe that in the future the practice of medicine will be largely a practice of dietetics.

Diet and Care of the Bowels in Typhoid Fever

DR. M. H. FUSSELL, Philadelphia: The clinical and autopsy evidence at command proves that a regulated milk diet does not irritate the bowel; neither does a diet of milk reinforced by carefully selected and prepared carbohydrate and nitrogenous diet other than milk. Common sense must be applied to both, and both may be used; but in semi-unconscious or wholly unconscious patients the diet must perforce be liquid. It is well to give divided doses of calomel if the patient is seen in the first week, in order to remove any irritating substance which may remain in the bowel. After that, a daily evacuation must be secured by enemas if there is a tendency to constipation. If diarrhea occurs, food must be stopped or regulated. If it then persists a mixture of salol and bismuth should be given, or an opiate if it is excessive.

DISCUSSION

DR. JAMES C. WILSON, Philadelphia: In typhoid, the great point is to treat each patient according to the special conditions of his case. It is often my custom to give a cup of coffee, more or less diluted with milk, in the morning, and then every two hours afterward milk in some form. I regard it as very important that the quantity should be moderate and that it should be taken very slowly. Various preparations may be employed, from time to time, such as junket, kumyss, custard and ice cream. In some cases bread may be given. I have never felt it desirable to give pieces of chicken, chops or beefsteak, as these would not be acceptable or be properly masticated. My position, I may say, is somewhere between the "liquid diet" and the "liberal diet;" sometimes a little more in the direction of one and sometimes the other. The rapid emaciation encountered in typhoid is, I believe, not a matter of diet, but due to the infection of the entire system; and it can not be wholly controlled by any kind of diet.

True Versus Spurious Opothrapy

DR. C. E. DE M. SAJOUS, Philadelphia: The title of this paper refers to true and pseudo animal extracts. By the "true" agents I mean those which can be used intelligently, that is, with knowledge of the physiologic effects produced,

because their active principles are known. Thyroid extract belongs to this class, since we know that its action is due to the iodine its secretion contains in organic combination. Adrenal preparations are, likewise, included, because their active principles, whether epinephrin, suprarenalin or adrenalin, are also known. Conversely, by "pseudo" agents I mean those animal extracts which are used blindly, without knowledge of their components, in almost any disease related directly or remotely with the organ from which the extract is obtained. Thymus and mammary extracts may be cited as examples of such agents. They are classed under the caption of "pseudo" until rendered fit by their sponsors, through chemical, pharmacologic and clinical researches, to be taken up by the profession as legitimate pharmaceutical agents. That so desirable a task is not impossible of accomplishment may readily be shown.

SYMPOSIUM ON PSYCHOTHERAPY

The Field of Psychotherapy and the Principles Involved

DR. MORTON PRINCE, Boston: There are certain principles, if not laws, which govern the functioning of the nervous system, namely: (1) Complex formation: By this is meant that associated ideas, feelings, emotions, sensations, movements, visceral functions of whatever kind, tend, after constant repetition or when accompanied by strong emotion, as well as under other conditions, to become linked together into a system or group in such fashion that the stimulation of one element in the group stimulates the activity of the rest of the group. Such a group is conveniently called a complex. The linking of functioning may be almost entirely of ideas or of physiologic processes, or of both. The path-breaking demonstrations of Pawlow furnish the key to the mechanism of many neuroses and psychoses, for the educated reactions of the gastric and salivary glands to ordinarily indifferent stimuli from the environment and to psychical states are in reality nothing but an artificially created psychoneurosis—a perversion of the normal reactions. (2) Conservation: By this is meant that all experiences (anything that has been thought, heard, seen or felt) tend to be conserved in the nervous system in such a way that they can be reproduced in a form approaching that of the original experience. This is the basis of memory. Conservation is fundamental for education, and on it the law of the linking of complexes depends. (3) Dissociation: This governs the normal psychoneurotic mechanism and is observed in a highly marked form in pathologic conditions. (4) Automatism: This plays a part in both normal and abnormal life. (5) Emotional energy: Intense sthenic emotions and feelings are accompanied by an increase of the vital functions, while certain depressive emotions are accompanied by a decrease of the vital functions. All these principles or tendencies are made use of in psychotherapy, which is educational in principle. We try to resynthesize the dissociated personality, from new healthy complexes, and organize them so intensely that they become a part of the organism and automatic.

Psychoanalysis in Psychotherapy

DR. ERNEST JONES, Toronto: In the first stage in psychotherapy, which most of the medical world is at present only entering, we clearly recognize that we have secured a new therapeutic weapon of the utmost value, which we may describe as the capacity to alleviate certain complaints by purely mental measures. A thoughtful person who employs any form of psychotherapy, however, soon realizes that a symptom which can be removed by mental measures is in all probability of a mental nature. Freud's psychoanalysis represents the second stage in the evolution of psychotherapy, and the psychoanalytic method is based on the knowledge that the symptoms present in the psychoneuroses owe their origin to a conflict between two groups of ideas which can not be brought into harmony with each other. One complex of mental processes is for some reason of such a kind as to be unacceptable to the main body of the personality. The personality, so to speak, fails to assimilate it, and the repressed complex then takes on an automatic existence and acts as an irritating foreign body. The central aim of the psychoanalytic method is to enable the patient to discover and appreciate the significance of the

mental process which manifests itself as a symptom. In carrying out this method several procedures may be adopted, according to circumstances. Under certain conditions the use of the hypnotic state undoubtedly has a legitimate place; but only a very few of those acquainted with the psychoanalytic method employ this at all extensively, as it has grave disadvantages. The procedure developed by Freud is the one most generally used, and gives by far the most satisfactory results. It is one of the ways of obtaining what is known as "free association," and is carried out by getting the patient to concentrate his mind on a given idea, generally in relation to a symptom, and asking him to relate truthfully in the order of their appearance the various thoughts coming to his mind. Among other valuable means of reaching buried mental complexes is the word-association method of Jung. By such ways the patient is able to free his personality from the constraining force of oppressing complexes, and, by taking up an independent attitude toward them, to gain a degree of self-control over his aberrant thoughts and wishes which was previously impossible. The method is thus in almost every respect the reverse of treatment by suggestion.

Simple Explanation as a Therapeutic Method

DR. E. W. TAYLOR, Boston: My aim is to show the possibility of the use of a psychotherapeutic procedure which involves no special technical knowledge and which is available for practitioners in all departments of medicine. It is a method which may be the means of alleviating many distressing conditions which simple encouragement can not accomplish. Its essential feature is the analysis of the mental state with reference to a search for the cause leading up to the developed neurosis. Many conditions regarded in their developed form as indications of an abnormal nervous system are, in reality, the normal reactions of a sound nervous system under special conditions of stress or misinterpretations of various events, in themselves innocuous. In the attempt to treat such cases the following general principles are suggested: (1) Diagnosis should be made; (2) this is best accomplished by allowing the patient to tell his complete story, rather than by a primary process of interrogation; (3) determination of the false point of view almost invariably reveals what has led up to the neurosis; the attempt is made to explain why such a series of events as that disclosed would be likely to lead to this result; (4) the patient having been impressed with the correctness of the physician's point of view, the process of readjustment begins, or, to use the more popular but possibly too comprehensive term, his re-education; (5) this is accomplished by pointing out in a painstaking manner the correct way to mental health, through a realization on the part of the patient of his previous misconceptions and through an accompanying effort toward the establishment of more rational mental adjustments.

Other Papers Read in This Symposium

"Psycho-prophylaxis in Childhood," by Dr. T. A. Williams, Washington, D. C.; "Character Formation in Relation to Psychotherapy," by Dr. J. J. Putnam, Boston; "Hypnoidal States and the Method of Hypnoidization in Psychotherapy," by Dr. Boris Lidis, Brookline, Mass.; "The Psychotherapy of Obsessions and Associated Conditions in So-called Psychasthenia," by Dr. J. E. Donley, Providence, R. I.

The Dietetics of Chronic Diseases

DR. WILLIAM H. PORTER, New York: All foods are divisible primarily into two distinct classes, the purely vegetable and the purely animal. Both these are divisible into five distinct groups of substances. Neither one is absolutely perfect in composition, but the animal class approaches more nearly to perfection than the vegetable. The animal class is more easily digested and assimilated, and it is also more economic, than the vegetable. To secure a perfect or ideal diet the two must be used together. Between the two extremes we have two other dietaries: one in which the two classes are blended perfectly, and one in which the two are less perfectly adjusted. The latter is often spoken of as a purely vegetable diet, while, in reality, it is a poor form of mixed diet; hence there is much

confusion in the minds of many who discuss the subject. When an ideal diet is secured, one which suits the individual case, marvelous results can be secured, and especially when this is used in conjunction with well-directed therapeutics.

DISCUSSION

DR. WOODS HUTCHISON, New York: As regards the dietary in chronic diseases, the attitude of late has been on the side of cutting down the amount of food; so that we are confronted with the danger of underfeeding. The bad effects of underfeeding are particularly noticeable in some of the races, like the Japanese and Chinese, who are accustomed to a diet lacking in the protein element. Consequently they suffer from such affections as beriberi.

The Effects of Modern Synthetics

DR. F. P. MORGAN, Washington, D. C.: The introduction of these synthetics has added very materially to the number of useful medicinal agents. Such substances, however, should never be recommended for general use until after they have been subjected to long and searching investigation. Even under these circumstances many of them appear to be peculiarly liable to produce occasional ill effects, and cases are not infrequently reported of the sudden and unexpected development of untoward results from the use of one or another of them. This seems to be particularly true of the group of substances commonly known as the coal-tar antipyretics. There can be no question as to their medicinal value, and I am of the opinion that whatever harm these agents may be doing to-day is not so much due to the drugs themselves as to the conditions characterizing their use. It can be said without hesitation that their promiscuous sale to the laity, which is carried on to an enormous extent in the form of headache powders, etc., is often productive of much harm. Reports from 400 physicians sent in reply to a circular from the Department of Agriculture show 814 cases of poisoning by acetanilid, antipyrin and acetphenetiden, with 28 deaths and 138 instances of habitual use.

Hypodermatic Medication in Modern Therapy

DR. S. L. DAWES, Albany, N. Y.: The administration of drugs hypodermatically is regarded as possessing distinct advantages over other methods, such as a more rapid rate of absorption, greater certainty of effect, quicker elimination, with less danger of cumulative action, and no derangement of the digestive processes. For several years it has been my custom to give all hypodermatic injections intramuscularly, rather than subcutaneously, my clinical observation having taught me that by this method the rate of absorption is much more rapid, the result more accurate, and the discomfort to the patient markedly less. That my conclusions are not at fault is borne out by the careful and accurate investigations of Meltzer and Auer made on rabbits. The occurrence of abscess, erythema, induration, or any other local disturbance in hypodermatic medication is almost without exception to be attributed to want of care or knowledge in selection of site and mode of operation, to unsterile instruments, or to unsterile, improperly prepared or preserved solutions.

Alcohol Injections in Neuralgias, Especially in Tic Douloureux

DR. O. G. T. KILIANI, New York: To Schlösser we owe the method of injecting alcohol with certainty into the trunk of the three branches of the fifth nerve, or, if necessary, into its roots. He employs alcohol, and in order to hit the nerve with certainty, advises that the injections be made into the foramina through which the different nerves emerge from the skull. Since September, 1906, I have thus injected alcohol into 190 patients with facial neuralgia, among which there were 5 failures. The other 185 were all entirely relieved of pain and of their anxiety over expecting pain (the mental effect is sometimes nearly as bad as the pain itself), and the average number of injections required was three to each patient. Of the 190 patients, 42 per cent. have had no recurrence to date. Taking into consideration the cases in which at least eighteen months have elapsed since the treatment, 21 per cent. of the

patients have remained free from pain for that length of time. In the other cases the time when the recurrence appeared varied from three months to two years.

Therapeutic Drainage in Two Hundred Cases of Uterine Obstruction. Presentation of a New Fenestrated Rubber Uterine Drain

DR. A. ERNEST GALLANT, New York: The relief of obstruction due to flexions and fixation has been accomplished by the following plan: (1) Stretching, by massage, of the bands or thickening whenever the uterosacral ligaments showed evidences of previous inflammation; painting the vault with pure ichthyol and tamponing the vagina every third day. (2) When the internal os is found tender to the passage of the sound, or the flexion is 90 or more degrees, forcible stretching of the adhesions under anesthesia, dilatation of the cervix, preferably by graduated sounds, and evertment of the mucous membrane, followed by irrigation of 1 to 2,000 potassium permanganate solution. (3) Introduction of a bivalve drain (in some instances suturing with silk gut) to remain for some months; a very necessary feature if permanent drainage and restoration of the cervix to its normal shape and caliber be desired. (4) Insertion in the vagina of a roll of gauze, its upper end being placed directly under the cervix, to serve the double purpose of a wick drain and uterine support. (5) The performance of trachelorrhaphy in instances of deep laceration into the fornices, and when the cervix is greatly hypertrophied and cystic.

Acapnia as a Factor in Disturbances of Function, and the Prevention of Acapnia

DR. YANDELL HENDERSON, Yale Medical School: For the proper performance of the various functions it is essential that the amount of carbon dioxide should be uniformly maintained. The object of the respiration is for this purpose, and the name acapnia has been given to the diminution in carbon dioxide met with in excessive respiration. I believe that acapnia is the cause of surgical shock, though this has not yet been proved. To avoid it in operations the initial stage of anesthesia should be made as short as possible, and it is equally important to bring the patient out of anesthesia without excessive respiration. Again, in laparotomies the exhalation of carbon dioxide from exposed viscera has been found to be forty times as great as that from the skin, and this should be prevented by keeping the organs protected by means of some impervious covering.

Other Papers Read

Other papers read at the meeting were the following: "Superficial Dermatitis of the External Auditory Canal," by Dr. C. J. Blake, Boston; "Medical and Surgical Treatment of Senile Enlarged Prostate," by Dr. O. C. Smith, Hartford, Conn.; "The Therapeutics of Some Obstetric Conditions," by Dr. B. A. Cheney, New Haven; "Recent Investigations as Related to the Therapeutics of Cardiac Arrhythmias," by Dr. T. E. Satterthwaite, New York; "Pain: Its Diagnostic and Therapeutic Value," by Dr. E. D. Fisher, New York; "Treatment of Stokes-Adams Syndrome," by Dr. R. W. Wilcox, New York; "Therapeutics of Calcium Creosote," by Dr. L. Kolipinski, Washington, D. C.

MONTANA STATE MEDICAL ASSOCIATION

Thirty-first Annual Meeting, held at Missoula, May 12-13, 1909

The President, DR. I. D. FREUND, Butte, in the Chair

Inability to Diagnose Appendicitis the Real Reason for the Mortality of Complications

DR. W. L. BISHOP, Butte: The mortality of appendicitis is in reality the mortality of the complications. Differentiation of the symptoms of uncomplicated appendicitis from the symptoms of complicated appendicitis is an urgent necessity. It should be impressed on physicians that the majority of cases are atypical and have only the one sign—tenderness—in common. The diagnosis should be made from tenderness alone, and operation should be advised in every case presenting localized tenderness.

Extrauterine Pregnancy

DR. E. F. DONDS, Missoula: Extrauterine pregnancy is of great importance to the man in general practice. Early recognition and prompt treatment are of the utmost importance. Mistakes in diagnosis are frequent in the early stages. Opinions of surgeons as to the best manner of treatment of this condition differ widely in relation to: (a) Shock; (b) hemorrhage. In nine cases which occurred in my practice, all the patients were operated on; eight by the abdominal route, one by the vaginal. In this last case there was hematocele. One death occurred after repeated hemorrhages.

Need for State Supervision and Care of the Consumptive

DR. MARY B. ATWATER, Helena: Six per cent. of all deaths in Montana are due to tuberculosis. All the older states have laws in regard to the prevention and control of this disease and Montana should not fall behind. One great means of prevention is found in the laws requiring inspection of school children, teachers, and schools. The state provides for the education of its citizens, it should also take cognizance of their physical welfare. Health and education should go hand in hand. There should be medical inspection of schools not only for the welfare of the children but for the protection of the community. Children showing a hereditary tendency to tuberculosis should be watched and guarded; those already infected should be placed in special outdoor schools. America is one of the last of civilized countries to appreciate the need of legal supervision of the tuberculous patient. Since impure milk and diseased meat are generally accepted as two of the chief causes of tuberculosis, the inspection of cattle is one of the most important problems confronting us to day. Two per cent. of all range cattle are said to be infected and of dairy cows a very large percentage are said to be affected. Besides strict laws for the inspection of meat and milk supply we need an efficient and sanitary street cleaning system—the streets should be flushed, not swept. We need medical inspection of schools—children, teachers, and buildings. There should be laws compelling the registration of every case of tuberculosis—laws which would enable us to handle a case of tuberculosis legally as promptly as we now do cases of smallpox or diphtheria. In order to do this the more advanced cases should be segregated and to do this we should have the legal right to place these patients where they can have proper care and cease to be a menace to the community. Physicians should interest themselves in politics and either go to the legislature or see to it that the men who are sent will enact the laws which the people of Montana need.

Advances in Bacteriology and the Present Status of Opsonic Therapy

DR. SAMUEL T. ORTON, Anaconda, read a comprehensive paper on this subject in which he touched on the following points:

Bacillus-carriers: Recognition of the fact of the occurrence of pathogenic organisms in healthy persons. The tubercle bacillus: its penetration of the intestinal mucosa in young guinea-pigs without causing a lesion and its presence in the blood and feces in human cases. The ocular and cutaneous tuberculin reactions: Description of methods; statistics and opinions. Yamagouchi's anaphylactic test for tuberculosis. Balanced toxin-antitoxin mixtures: Theobald Smith's observation on active immunity induced by this method. The *Sprochoarta pallida*: dark-field method; inoculation experiments. Serodiagnosis of syphilis: Description of methods of Wassermann, Pooges and Klausner; discussion of reactions in syphilis and the parasymphilitic diseases. Flexner's antimentingitis serum. Hiss and Zinsser's observations and experiments with leucocyte extracts. Opsonic therapy: Definition; theories; autogenous vs. stock vaccines; index reading vs. clinical method of control; diseases amenable to vaccine therapy.

Legal Regulation of Midwives and Importance of Proper Care of the Obstetric Patient

DR. W. H. JOHNSON, Billings, discussed physicians and legislative matters in general and laws relating to midwifery in particular. Among other things he said: Physicians should take more interest in the laws relating to the practice of medicine and the regulation of midwives. In Montana there are many women, neither physicians nor trained nurses, who, without a license or training of any kind are permitted to

visit, examine, and deliver or attempt to deliver pregnant women. While I must admit that 75 per cent. of all such patients could deliver themselves if left absolutely alone, there are, on the other hand, the other 25 per cent. who need assistance in some form and it is impossible to determine who those may be without examination; and while it is not in every case that a midwife ever goes so far as the examination there are those who do so and do so repeatedly and with absolutely no heed to asepsis in any way. We can all remember the time when sterile gowns were made to take the place of the duty kitchen apron, and how he who advocated the plan was made the subject of many a jest as well as he who fought for the rubber glove in this kind of work, and I would like to say that not the midwife alone deserves criticism for uncleanness but many physicians as well who are regardless of the laws of asepsis and antisepsis. They will rush into a confinement with no thought of surroundings and personality, and attempt the delivery of women, even in forceps cases, who are surgically unclean and for whom, except in a life-saving measure, nothing should be done until aseptic precautions have been taken. It is more probable for septicemia to occur in this region than any other except possibly the peritoneum, and still we watch the dangerous work go on without one single word of protest. We allow the midwife to visit the woman in labor with the same clothing worn while on a recent visit to a contagious case, be it diphtheria, measles, scarlet fever or typhoid; or the busybody may have dressed a suppartion somewhere in the neighborhood and without a single preparation except a little soap and water on the hands, proceed to examine the woman about to be delivered. Is there any plausible reason why obstetrical patients should not have the same preparation accorded to surgical patients? I believe that many physicians become exceedingly careless about these important points and do not realize until too late that measures of extreme importance have been overlooked. I wish to emphasize the necessity for more precise and thorough work among physicians and a compulsory course and state board examination for midwives. I believe that we have no such regulations at the present time concerning midwifery and if such be the case the Montana State Medical Association should lose no time in setting the matter right. It ought to be the duty of every physician to use trained nurses in all confinement work or else to instruct his patients in regard to all utensils and dressings, and the method of thorough sterilization and to see that his instruction is scrupulously adhered to.

"Alcohol as a Cause of Disease and the Relation of the Physician to the Alcohol Problem," by Dr. H. F. Canaan, Anaconda; "Higher Education," by Dr. Dennison, State University of Montana; "Diplococcal Infections of the Skin," by Dr. H. D. Kisdler, Butte; "Nervous Influenza and Nervous Conditions in Women," by Dr. J. R. E. Quires, Butte; "Some Suggestions in Regard to Hernia Operations," by Dr. T. C. Witherspoon, Butte.

NORTH DAKOTA STATE MEDICAL ASSOCIATION

Twenty-second Annual Session, held at Fargo, May 11-12, 1909

The attendance was about as large as there has been at any annual meeting. The program was replete with papers that were unusually good and instructive and the discussions were spirited and entertaining. Papers were also contributed by the following invited guests: Drs. A. McLaren, A. Gillette and T. W. Stumm of St. Paul, Minn. Dr. Stumm delighted his hearers with the masterful way in which he portrayed an uncompensated heart.

Organization

It was a source of gratification to find more physicians reported as in good standing than at any previous time. The lame part reported in organization seemed to be a lack of active work by the councilors who up to the present had not risen to the height of their opportunities. It was stated that so many physicians had not affiliated with the local societies that recruiting would be necessary and that the additional labor would fall on those who have been elected to counsel and advise and boost the membership.

President's Address

The President, Dr. H. A. Beaudoux, Fargo, congratulated the officers of the district societies for their untiring effort to interest and bring in new members, and to make the meetings instructive and profitable. He recommended such post-graduate courses as might be authorized by individual societies or according to the plans offered by the American Medical Association. He advised the invitation of laboratory men who, through the opportunities offered, could bring to the meetings new stimuli and special knowledge. In districts where distances are great and railroad communication inconvenient, the organization of sub-societies, subsidiary to the district societies to which they geographically belong, to meet with the district society annually for the purpose of making their report and participating in the election of officers. The profession as a whole, out of consideration for the public which it is to safeguard, should be awake to its manifold duties in sanitary legislation, anti-charlatanism and prophylactic measures of all kinds. Each member of the profession should consider himself a health officer in preventing the pollution of streams and the spread of disease to innocent people. The easiest way to rid a community of pollution is by preventing it, and this is much easier in a new community than in the older ones where it is already widespread. The echo of that great scientific body which met last fall in Washington, D. C., had barely faded away when the country, quickened by its deliberations, and believing in the earnestness of its participants, began an active campaign against our common foe. "Antituberculosis" has been the cry and the wave of education which is sweeping state by state has led us to believe that we are fully awake to the importance of Koch's discoveries and that we as an intelligent people have determined to rid ourselves of that plague. The North Dakota State Board of Health sought an appropriation for an antituberculosis crusade and although it was denied by the legislature, the secretary of the board, with the director of the state bacteriologic and pathologic laboratory, Dr. G. R. Ruediger, has nevertheless almost completed these preparations and planned a most thorough and efficient campaign through the state. To further and promote state legislation and appropriation and to assist the State Board of Health in carrying on its work unhampered, as well as to assist the committee on public policy and legislation, it has become necessary that as physicians we realize our position and medical influence in such matters. The members of the present legislative committee, well-trained and efficient in their work pertaining to such demands, have not met with the success they had hoped for, not because they are inactive or inefficient but from the fact that legislators like the great majority of the laity look on medical legislation from a commercial standpoint and through lack of education and appreciation of our work are too prone to label our demands with the stamp of personal greed and gain. We should return to our homes with the determination of impressing our prospective representatives with the importance and benefit of our work and if necessary to make our demands a political issue. By so doing we shall attain far better results than we have in the past by sending a body of medical men to the capital on the eve of defeat. We are better equipped to pass sane and important legislation than any other body of men and to make ourselves felt in public matters owing to our intimate relations, as family physicians and advisors, with the voters throughout the state. There is not a man who enjoys the confidence of his patients who can not in a few words convince him that what is being asked by the medical profession, is for the benefit of all with special privileges to none. Let us therefore trust that before we leave this meeting the sense of this society shall be that we are determined to bring such influence to bear on our representatives as may be necessary to secure the legislation recommended by this society as well as outlined by our legislative committee. One of the most important legislative acts which is focusing the attention of the intelligent people everywhere is the sterilization of defectives and habitual criminals as a necessary measure of social economy. Statistics show that the mentally defective classes, natural criminals, imbeciles, insane, and epileptics, have multiplied in the last thirty years more than twice as fast as the total population. The question has arisen in the past of the advisability of publishing our transactions in connection with some adjoining

state and to make their journal the mouthpiece of this association. It has occurred to me that there is no reason why we should not only publish our transactions but also edit a quarterly if not a monthly journal of our own. There is certainly ample material and brain and, it goes without saying, pride in this society to carry such a plan to a successful issue both scientifically and financially. The material from our annual meetings together with the report of committees, papers read at the different district societies with the work and report of the state board of health and state laboratories would provide ample interesting material if properly prepared.

The House of Delegates

The advisability of publishing a journal was considered, and while it was thought to be desirable to have such a medium in the state, the financial support was considered inadequate for such an undertaking and the project, with not a few advocates in its favor, was deferred. These resolutions were considered and approved:

Resolved: That this association heartily approves the action of the Board of Trustees in restricting advertisements of medical preparations to those approved by the Council on Pharmacy and Chemistry of the American Medical Association; and further be it

Resolved: That this House of Delegates requests all those state associations which now do or hereafter may publish or control medical journals to restrict their advertisements to such approved preparations, and that the General Secretary be requested to bring this resolution to the attention of all state associations.

The legislative committee was instructed to formulate and present at the next annual meeting some practical plan for the care of such medical legislation as would come before the next legislature for enactment. The sterilization of criminals and other defectives by vasectomy was considered and recommended to the careful consideration of the law makers of the state and referred to the legislative committee.

The committee on tuberculosis made an exhaustive report and requested that in the future it be permitted to work in conjunction with the public health committee of the state, the work being along similar lines—it was thought best to consolidate effort in the hope of achieving better results, and then request was granted.

APPROPRIATION FOR CARROLL FUND

The matter concerning the conditions under which the widow of Dr. James Carroll, Major and Surgeon, U. S. Army, is suffering was brought to the attention of the House of Delegates and on motion one hundred dollars was appropriated to assist in saving the home of the widow of this medical hero, whose self-sacrifice contributed so greatly toward the control of yellow fever.

DELEGATE TO PHARMACOPEIAL CONVENTION

The president was authorized to appoint a representative to attend the United States Pharmacopeial Convention to be held in Washington, D. C., May, 1910.

A list of the officers elected appeared in THE JOURNAL, May 22, 1909, p. 1674.

SOUTH CAROLINA MEDICAL ASSOCIATION

Sixty-first Annual Meeting, held at Summerville, April 20-22, 1909

The meeting of the county secretaries was held on the morning of April 20. The object of this meeting, as stated by the president, was to effect the organization of the county secretaries into a body which would eventuate in better work being done throughout the state. The name and county of each secretary was enrolled. A number of talks were made, the president emphasizing the point that the secretary was "the man who did the work," and was therefore the most important man in the county society. The president also earnestly recommended, as did several others, that the county societies report important cases to the state association, and also that the discussions on these papers be taken down by a stenographer.

A card index system was adopted, by which monthly reports could be sent in to the state secretary.

The by-laws of the Missouri county secretaries were adopted, with a few modifications, and the time of meeting was set as the morning of the first day of the session of the state association.

Chairman, vice-chairman and secretary-treasurer were elected, and an executive committee, composed of five members, of which the secretary and treasurer of the state association are members ex-officio.

A committee was appointed to read papers at the next meeting on work pertaining to the organization.

Relationship Between the County Secretary's Office and the State Secretary's Duties

DR. WALTER CHENEY, secretary of the South Carolina Medical Association and president of the National Association of State Secretaries: The relationship between the state secretary's office and that of the county secretary's should be that of father and son, so to speak; there should be intimacy and that courtesy which should be extended to true relationship. Each county secretary should see that every man's name in his society is on file in the state secretary's office, etc.

Officers Elected

A list of the officers elected appeared in THE JOURNAL, May 8, 1909, p. 1506.

Educational Plans and Methods to Improve Sanitary Conditions

DR. S. C. BAKER, Sumter, in his presidential address, emphasized civic healthfulness, not only from the viewpoint of benefit to the individual, but to the state and nation. His plea was for the establishment of conditions that would not only alleviate the ills of present sufferers, but would safeguard unborn generations by the elimination of the possibilities of ill. For this reason he emphasized the need of restricting marriages between parties with blood taint. Imperfect drainage, water, food, house ventilation and isolation in contagion were also noted. He also spoke in behalf of improved and advanced medical education; first in behalf of South Carolina, then for the whole country. He advocated hospital internship or a year of general practice before postgraduate courses. Loyalty to and patronage of state institutions or hospitals he deemed the wisest and best way to afford mutual upbuilding as well as state wide confidence on the part of possible patients. This carried with it the idea of personal research. In speaking of alcoholic beverages, he said:

"The question of the further limitation of alcoholic beverages has become almost a national issue. The wisdom of its forcible curtailment we will leave with the prohibitionist, the politicians and the people. We recognize the evils of over indulgence. I believe that the craving for liquor is greatly augmented by the general depletion of our vitality. This question is one that intimately affects our people, and we are as competent to test and solve it as any. Let us, then, endeavor to work out the cure for the inebriate, but let us go further and solve the problem of how to eradicate the tendency to inebriety. At the same time we might strive to curtail the evil of gluttony, as one which possibly is filling more graves than whiskey."

With regard to the new cults, faith or semiprofessional, Dr. Baker urged leniency with watchfulness, since many individuals have been shown to have been relieved even when treatment by regular practitioners seemed to have failed. He paid marked tribute to the physicians and surgeons of the South, whose talents and energies have become known world-wide in the history of professional benefaction. Referring to the approaching centenary of Dr. J. Marion Sims of Lancaster county, S. C. in 1913, Dr. Baker recommended the erection of a monument within his native state, to honor appropriately a man whose labors have brought so much of relief into the world.

He suggested that a prize be given every year or two years for the best work in original research within the borders of South Carolina by a member of the association.

Tropical Diseases in the Canal Zone

DR. HAYNE discussed briefly the commoner tropical diseases that are met with on the Isthmus: Yellow fever, beriberi, leprosy, dhobie itch, elephantiasis, tropical neurasthenia, malaria, ankylostomiasis, dysentery and liver abscess. He

demonstrated the thoroughness with which the Panama sanitarians are destroying the breeding places of the anopheles, screening all the houses and using quinin prophylactically. He emphasized the routine examination of the stools. Ankylostomiasis, he said, was fast being eliminated with thymol. In Panama they had accomplished a first great step in the dysentery problem—the certain diagnosis of the amebic variety with its sequel of liver abscess. Dr. Hayne showed that the field of tropical medicine was a wide one and emphasized the need of a knowledge of zoology for the southern practitioner.

Problem of Pacific Quarantine, Which Will Apply to the Atlantic Coast When the Canal Is Completed

DR. COFER, P. A. Surgeon United States Public Health and Marine-Hospital Service: The Pacific is like a wheel, with ports all around the rim, and with lines of travel crossing it like spokes. These ports are centers of population and distribution, that may either import or export disease, as well as merchandise. The quarantinable diseases are yellow fever, smallpox, cholera, typhus and leprosy. Except typhus, these are more or less prevalent in South America and Western Asia. The non-quarantinable diseases are scarlet fever, diphtheria, amebic and bacillary dysentery, beriberi, trachoma and ankylostomiasis. The shorter the time of the voyage, the shorter the stay in port, the larger and higher out of the water the vessel, and the more completely the different parts of the vessel are separated, the less danger of carrying diseases. Hence, from a sanitary standpoint, steamships are vastly superior to sailing vessels. The tramp sailing vessel is the most dangerous; the army transport least so, because carefully inspected. As commerce increases between the South Atlantic ports and those of South America and Western Asia, it is possible we may send them malaria and yellow fever, in exchange for plague, cholera and leprosy. Quarantine is, at present, very efficient. Vessels are inspected, and at times disinfected or quarantined on leaving port, on entering port, and sometimes on the way. The condition of the public health of all ports is regularly reported to the surgeon-general of the Public Health and Marine-Hospital Service. Greater marine sanitation will be necessary when these ports communicate with the Pacific through the canal. The number of visitors will be increased, as well as insanitary, foreign population, living along the water-front. The Pacific ports have taken this matter up. The quarantine is a burden to commerce, but they realize that the better the sanitation, the less need for strict quarantine. However efficient the quarantine, occasionally an infected mosquito or rat will reach shore. If municipal sanitation against these pests is effective they will do no harm. If it is not effective, they will start an epidemic of yellow fever or plague.

The Common House Fly

DR. F. A. COWARD, Columbia: The house fly forms 98 per cent. of diptera in the civilized world, and is world-wide in distribution. Its only useful rôle is that of scavenger—which is of negligible value when compared to its annoyance and dangerous filth and disease-carrying habits. Its preferred breeding place is horse manure, the excrement of other animals, and human beings; decaying vegetable matter will serve, when proper warmth and moisture coexist. Ten-days suffice for development of a brood; fifteen broods a season are possible in South Carolina's climate. Twelve flies surviving the winter may reproduce 40,000 during the following warm season. Two hundred larvæ have been observed in one cubic inch of manure. The fly's life is but a few weeks, but in a dormant stage it may live through the winter in closets and warm parts of houses. Efforts at extermination should be made through the cold season—to catch the relatively few hibernating insects. Traps, sticky fly paper, poison, and killing by hand are recommended.

Address on Surgery: Urogenital Tuberculosis

DR. BRANSFORD LEWIS, St. Louis: An easier, clear conception of urogenital tuberculosis is obtained when the general scheme or plan of attack on these organs by the infection is

understood. Transmitted in any one of five different ways, the tubercle bacilli reach the urinary or genital organs; certain of these organs habitually receive the brunt of the attack first, while others invariably stand secondary in this respect. In the majority of cases, one or the other kidney is the organ first attacked; in a small proportion an epididymis is the point of initial attack. From these respective foci the infection spreads in the direction of the physiologic secretions (the urine and semen); that is, from the kidney downward, along vas deferens, seminal vesicle, ejaculatory duct, prostate and urethra to the vesical neck. Thus the bladder stands in the line of secondary attack from either direction, and likewise stands a most excellent chance of ultimate infection, no matter how resistant it may show itself for a time. Vesical tuberculosis is therefore an affection invariably secondary to tuberculosis of some other urogenital organ; and must be so considered in respect to diagnosis, prognosis, therapy and management.

The marital relation is not considered an important or frequent factor in the transmission of tuberculosis, notwithstanding that coincidences of that kind are often reported. While demonstration of the tubercle bacillus is usually the crucial factor, its demonstration is not absolutely essential; and on the other hand, the presence of bacilli in the urine does not necessarily indicate vesical tuberculosis, as the bacilli may float for long periods in the urine of persons whose urinary tract is innocent of any pathologic lesion. All the staining methods in vogue for the differentiation between smegma and tubercle bacilli are liable to lead to error and disaster in diagnosis. In obtaining the urinary specimen for investigation, smegma bacilli should be absolutely excluded by cleansing methods and careful catheterization, no dependence being placed on the specimen passed voluntarily. Cystoscopy is the other necessary factor for fixing the diagnosis of vesical tuberculosis, and it should be employed for both diagnosis and treatment. I am decidedly opposed to the rather broadly disseminated view that urinary tuberculosis means interdiction of such instrumentation. The cystoscopic picture, while often characteristic, is not always typical or certain. The condition called lymphoid tubercle often simulates real tubercle, but without having any relation to Koch's bacillus. The positive evidence presented by the appearance of a ureteral orifice is valuable, but the negative evidence is of little import. Tuberculous kidneys have been removed in cases in which the corresponding ureteral orifice showed nothing abnormal to the cystoscope. The segregator is of little value, as compared with the more exact method of ureteral catheterization. The latter is free from the theoretical danger attributed to it, that of conveying infection into the healthy ureter. The treatment of vesical tuberculosis is divided into palliative and curative, by hygienic, systemic, local and operative measures. The modes of treatment embrace, besides general systemic and hygienic measures, tuberculin treatment, operation on the original foci of infection, operation on the bladder, without perhaps extirpation of the organ and transplantation of the ureters; curetting of the organ, with application of medicaments and drainage; local applications to the vesical mucosa; cystoscopy and ureteral catheterization, and applications into the bladder or ureters. The profession should no longer consider cases of urinary tuberculosis as beyond the reach of assistance or beyond reclaim. Many such patients are brought back to health and strength and comfort, both with and without operation. Tuberculosis of these organs is amenable to judicious care and treatment as it is of other parts of the body.

Sources and Modes of Infection in Tuberculosis

DR. M. P. RAVENEL, University of Wisconsin: For practical purposes, the only modes of infection that will be considered are through the respiratory and the digestive tracts. All the early experiments on respiratory infection were defective in the fact that no effort was made to prevent the swallowing of material inhaled, and much matter which entered by the nose finally reached the stomach and intestine. The tonsils are a frequent port of entry. It has been proved that the tubercle bacillus may penetrate the unbroken mucous membrane, without leaving any mark at the point of entrance. It

has been necessary to revise our ideas, in view of modern experiments which have shown that inoculation into practically any part of the lymphatic system may produce tuberculosis of the lung. It has also been shown that inoculation of tubercle bacilli into the tail of an animal may produce pulmonary tuberculosis. Experiments in feeding have demonstrated the same thing. Further experiments with the injection of the tubercle bacilli directly into the stomach through an opening in the abdomen have demonstrated that the tubercle bacilli can arrive in the lung in large numbers within from three and a half to twelve hours. The route from the intestine to the lung is through the thoracic duct, and after entrance into the blood, the tubercle bacilli are retained in the capillaries of the lung through the filtration action of the lung. Two principal sources of infection must be recognized. The chief danger to man is the tuberculous man. Careless expectoration is probably the chief mode by which human tubercle bacilli are distributed. Tuberculous cattle infect a considerable number of persons. Of 306 cases of human tuberculosis including those given by the German Imperial Commission and British Royal Commission, 63, or more than 20 per cent., were due to bovine bacillus. Of the 84 children examined by the German commission, 21, or 25 per cent., showed infection by the bovine bacillus. The physician who allows a child to drink the milk of a tuberculous cow is criminally responsible. It is a duty of cities and states to enact laws requiring that all dairy cattle shall be tested and found free from tuberculosis. In stamping out the disease, both sources of infection must be taken into consideration. If only one is considered, the work will be incomplete.

Retropharyngeal Abscesses

DR. E. W. CARPENTER, Greenville: This is a rare surgical affection of the throat, more prevalent in children, and while the symptoms are prominent, they are often misinterpreted. Medical literature contains very few mentions of the condition, though it was described as early as the second century of our era, by Galen. The points emphasized are the necessity for early recognition and correct method of treatment.

Pellagra

DR. G. A. NURFLER, Abbeville: The treatment of the majority of these patients is interesting, in that it is on somewhat original lines. Hydrogen dioxide was used internally for the relief of gastrointestinal symptoms, while at the same time arsenic was given for the skin lesions. The most important pathogenic symptom was pellagial erythema, which appears almost always in the spring and attacks the exposed surfaces. Pellagra is not contagious or communicable. Its immediate cause is supposed to be the use of diseased maize, which forms a toxin. Bad hygienic conditions, lack of proper food and exposure to the sun are the essential requisites for the contraction of the disease. There are digestive troubles in connection with the cutaneous manifestations—dyspepsia, pyalism and diarrhea, which is frequently of a dysenteric nature. The milder cases improve after a few months, there being apparently a complete recovery during the winter. In the more severe forms there are pronounced nervous symptoms: headache, backache, spasms and then paralysis and mental disturbance. Suicidal mania and melancholia are frequently encountered in the third and fourth attack. There is rapid emaciation and the mucous surfaces from the mouth to the anus are affected, the tongue becomes red and denuded of epithelium and the gums swollen and sore, the genitalia are also affected, the vagina and cervix are red, inflamed, and itch, and there is considerable discharge. Usually there is elevation of temperature. This disease is rarely seen save in the poorer classes, and in women between 30 and 50. In the first case here reported stomatitis was diagnosed, but treatment for that did no good. This patient was seen in 1906. There was an eruption on the back of the hands, and fever ranging from 100 to 102 F. The tongue was red and slick and there was pain over epigastrium, etc., finally resulting in acute mania. Consulting physicians could not make diagnosis. Patient died three months after being seen. The second patient, a negroess of 27, there were the same clinical symptoms, and about the same

treatment was given. The patient grew steadily worse and another physician called in failed to effect a cure, patient dying in three months. There was acute mania for several days before death. The third patient, 50 years old, complained of sore mouth, and medicine did no good. There were characteristic symptoms, but no typical eruption on backs of hands. Patient died in a short time. There was intense nausea all the time. A fourth patient, aged 40, had suffered for some years with articular rheumatism. In 1907 she had what she supposed to be "chapped hands." On May 3, 1908, she complained of dysentery and sore mouth and was treated for several days without improvement. Then eruption appeared on the backs of hands. Consulting physicians thought she would not live longer than sixty days. A mouth wash of hydrogen dioxide had done her good, and this suggested internal treatment. I gave 15 drops in water every three hours. She began to improve at once, and one month later all symptoms of pellagra had disappeared. The patient is living and is kept on tonic of iron, quinin and strychnin. All maize products are forbidden her and a generous meat diet is given.

The Surgical Significance of Angiosclerosis in the Eye

DR. CHARLES W. KOLLOCK, Charleston: I wish to emphasize the importance of the early recognition of the causes of disease, in order that preventive treatment may be pushed at a time when most useful and necessary. It is important to make a careful study of the retinal vessels in all cases in which sclerosis might be present. Arteriosclerosis, however, may affect vessels in one part of the body and not another; one portion of a vessel may be affected and the other not, but when sclerosis of the retinal vessels is present in many instances it exists also in the smaller vessels of the brain. Stengel has said that even more important than the four well-known facts for increased arterial tension, is a knowledge of the conditions of the retinal vessels as seen by the aid of the ophthalmoscope. The "corkscrew twigs," flattened veins, "silver wire" arteries and hemorrhages are signs of arterio sclerosis that are never wrong, and are, in most cases, a reliable indication of the condition of the vessels of the brain. A most careful search should be made for the above conditions in all persons over the age of 40. Great risks are taken by those who, when in need of glasses, consult an optician or refractionist, rather than an educated physician who not only understands the art of refraction, but also knows and appreciates the importance of a thorough ophthalmoscopic examination.

The Campaign Against Tuberculosis

At the meeting of the antituberculosis committee, on April 20, in connection with the state association, encouraging reports were made with reference to the work of the organization.

Dr. Dawson, chairman of the state antituberculosis committee, presided over the meeting. The following is a brief outline of his report to the association:

At a meeting held in Columbia, Oct. 29, 1908, the committee of the South Carolina Association for the Study and Prevention of Tuberculosis was organized. A standing committee was appointed, consisting of one member from each county inside of the state of South Carolina. Members of such committee were instructed and empowered to organize, in their respective counties, such organizations to consist both of laymen and physicians, to aid and cooperate in the fight against tuberculosis, and also to instruct, so far as possible, the public in general as to the method of conveyance of tuberculosis, as well as its prevention and cure. The aid of civic clubs was also invoked and arrangements were made that the poorer classes would be visited and instructed in their homes. It was provided that this committee meet annually on the day before the regular meeting of the state association, at such a place as that organization should have chosen for its annual meeting.

Reports from sixteen counties were made and funds were raised by applying to the state legislature for an appropriation in Sumter county. In several other counties individual subscriptions have contributed a sufficient fund for next year.

OHIO STATE MEDICAL ASSOCIATION

Sixty-fourth Annual Meeting, held at Cincinnati, May 5-7, 1909
(Concluded from page 1688)

A New Method of Gastroenterostomy

DR. EDWARD A. HAMILTON, Columbus: In doing this operation, a portion of the posterior wall of the stomach is pushed through the transverse mesocolon in the usual way and together with a loop of the jejunum is surrounded by an ordinary rubber catheter. The catheter is held firmly to the enclosed tissues by two rubber-sheathed hemostats to keep the parts from slipping through the rubber loop. A circular portion of the stomach wall and an oval part of the intestine are excised, these openings are then joined by a single suture of von Brun's linen inserted by the Connell method, which makes a firm and substantial union, bringing into the bite of each stitch all the coats of the bowel, so that leakage need not be feared. I have forced water under considerable pressure into the stomach and intestines so joined, and found that even in the cadaver this stitch makes a water-tight joint, and as peritoneal exudate occurs in the living in four hours so strong as to wall off liquids, the fear that one row of sutures may not be strong enough is groundless. There is nothing to prevent a reinforcing outside peritoneal layer of sutures if there is any fear that the line of union is not sufficiently firm.

Ocular Signs of Arteriosclerosis

DR. WILLIAM E. BRUNER, Cleveland: Study of the retinal vessels is important in ascertaining the condition of the general arterial system. Some of the ocular symptoms are: (1) Tortuosity of the retinal vessels; (2) irregularity in the caliber of the retinal arteries; (3) "silver-wire" appearance of the retinal arteries; (4) loss of translucency in the vessels; (5) compression of the veins by overlying arteries; (6) white lines along the vessels; (7) edema of the retina; (8) retinal hemorrhages; (9) thrombosis of the central retinal vein or some of its branches; (10) obstruction of the central artery or some of its branches; (11) spasm of the retinal artery; (12) lesions of the optic nerve, as congestion or edema of the nerves, retrobulbar neuritis and optic atrophy; (13) glaucoma; (14) paralysis of one or more of the ocular muscles; (15) lenticular opacities; (16) vitreous opacities; (17) subconjunctival hemorrhages; (18) asthenopia.

Submucous Incision for Reduction of Hypertrophied Turbinals

DR. C. P. LINHART, Columbus: The method of establishing a permanent reduction of hypertrophied turbinals is as yet an unsolved problem in nose surgery. Cautey and caustics are transient in their effect and have to be repeated. The removal of a section of the inferior turbinal destroys a part of an important functioning membrane, and, while it permits the passage of air through the nose, it does not give the anticipated improvement of the condition. The chief advantages of submucous incision is that it shrinks the vascular tissue of the turbinals, allowing free respiration of air through the nose; cutting across the walls of the venous sinuses causes their obliteration, and a permanent shrinkage results from the inflammatory adhesions; the base of the scar is on the turbinate bone, the seat of greatest traction; there is no destruction of mucous membrane, and no open wound to heal by granulation; it requires but a short time for surgical treatment (usually two or three days), and on account of no destruction of mucous membrane, there is no interference with the physiologic functions of the nose.

Radical Operation for Cancer of the Uterus

DR. J. H. JACOBSON, Toledo: The chief reason for the high primary mortality accompanying the radical abdominal operation for uterine cancer may be summed up in one word, "shock." The various factors concerned in its causation may be eliminated for the most part by the employment of spinal anesthesia, which I consider especially adapted for this operation. The afferent impulses or sensations can not be referred to the peripheral vasomotor centers and nerves, and thus produce shock. Spinal anesthesia may be said to be about

as safe as chloroform, but more dangerous than ether. The roentgenologist should, if possible, witness the operation, in order that he may plan the after-treatment to the best advantage. About forty very thorough exposures are made in the after treatment with the x-ray. The points in favor of the postoperative x-ray treatments are: (1) The ray has been shown that certain superficial forms of cancer are amenable to cure by its employment; (2) theoretically it would seem that if the pelvic structures could be technically rendered superficial, and directly accessible to the ray, the same results could be accomplished here as are obtained elsewhere; (3) the ordinary x-ray treatment of uterine cancer has heretofore been tried and proved a failure, but not so with postoperative treatment with the x-ray; (4) the technic, when properly applied, allows of direct treatment of every part of the pelvis, the dose can be easily regulated, and the tubular lead glass speculum, when properly directed to all parts of the vaginal fornix, permits of a systematic and thorough exposure in every direction; (5) cancer of the uterus does not have a tendency to metastasis into other organs as other forms of cancer; (6) it is now an established fact that recurrence after the vaginal operation for uterine cancer occurs in the vaginal cicatrix, whereas in the abdominal radical extirpation the recurrence is usually in the lymphatic glands of the pelvis. The main object of the paper is to emphasize the good results which are obtainable by the radical abdominal extirpation for uterine cancer and to make a plea for its more general employment; no other operation is comparable to this method; further, that spinal anesthesia greatly reduces the mortality, and that thorough systematic postoperative x-ray treatment can be effectively employed.

DISCUSSION

DR. H. G. SUTTON, Zanesville: I doubt the advisability of carrying out such extensive dissection of neighboring parts as would necessarily be required in the radical abdominal operation for uterine cancer advocated by Dr. Jacobson. I have met men with large experience, men of no mean ability in this country doing abdominal surgery, but they have never been able to satisfy me that they could diagnose uterine cancer by the microscope before it can be done macroscopically.

DR. R. B. HALL, Cincinnati: I do not think it right or just, or the best thing for the patient, to advocate this extensive dissection, enucleating all the glands by dissecting up the ureters, for carcinoma of the cervix, because the primary results following vaginal extirpation of the uterus are better and a larger percentage of the patients recover. High mortality attends the abdominal radical operation as compared with the low mortality attending the vaginal method of dealing with such cases. The ultimate results of this wide dissection are not so very much better regarding prevention of recurrence than vaginal extirpation. In almost all the patients there is recurrence and they die, no matter which operation is done.

DR. EDWARD RICKETTS, Cincinnati: In waiting until a cancerous nodule can be detected in the cervix or in the uterine walls, Dr. Jacobson in reality advocated a late operation, when the best results are to be obtained by early operation. But even at that I can not consistently advocate such wide and extensive dissections. I consider them beautiful from a scientific standpoint, but disastrous from a practical one. Some men get good results from the method of simple extirpation, while others get equally good results from the swallow tail operation as advocated by the late Dr. T. A. Reamy. Shock from the vaginal operation is far less severe than from the radical abdominal operation.

DR. GEORGE W. CRILE, Cleveland: Cancer of the uterus should be considered from the standpoint of each individual case. For instance, cancer of the fundus in its early stage is a curable disease. There ought to be a difference made in the prognosis as to the location of the growth as well as to the degree of its advancement. Cancer of the uterus, as a rule, gives a favorable prognosis, but like cancer of the breast, and elsewhere, the virulence of the disease itself can not be predicted. Sometimes a small cancer of the breast will be fol-

lowed by internal metastasis in a very short time, while a much larger growth in the same region may not show metastases at all. In late cases of uterine cancer I think simple curettement of the tumor mass the wiser procedure, but in those cases in which a radical operation is to be considered, the very large statistics available should lead us to give preference to the abdominal radical method rather than to the vaginal method. With the vaginal method there is more liability to force the cancer cells mechanically into adjoining tissues. With the radical abdominal method I have been able to obtain a three years' cure in about 24 per cent. of my operations.

Traumatisms of the Sacroiliac Joint and Their Sequelæ

DR. ROBERT CAROTHERS, Cincinnati: The sacroiliac joint is a true joint, known to be subject to the same diseases as other joints, and movable ordinarily in a slight degree. It is subject, therefore, to a wrench or sprain, a true luxation, or a relaxation or looseness. In the first cases, the symptoms are usually diagnosed as lumbago, on account of the pain and limitation of motion in the back; pain may be in the back, thigh or leg. A correct diagnosis is sometimes confirmed by an x-ray examination. The luxation cases are rare, and are produced by some violent injury to the lower portion of the spine. The relaxed or loose sacroiliac joint is the most common, the least often recognized and more lasting and difficult to treat. When these patients present themselves they are confirmed neurasthenics. A diagnosis is to be based on inspection, pain, limitation of motion, and mobility. Rectal examination will not infrequently elicit a tender point on either or both sacroiliac joints. It is to be differentiated from sciatica by absence of pain on pressure along the sciatic nerve and the presence of the signs enumerated. In the same way it is to be differentiated from lumbago by the absence of pain on pressure over the lumbar muscle, free motion of these muscles, and the presence of the signs of sacroiliac injury. In the mild cases, massage, properly directed exercises, stimulating baths and electricity often improve muscle tone and add materially to retention thereby of a relaxed joint. More severe cases require the application of some form of retention apparatus, and probably the simplest is the adhesive strap. When this fails a proper support of elastic webbing may be used. In extreme cases some mechanical brace will be necessary, which should be devised with special reference to holding the pelvis securely, grasping the trochanters and making some pressure on the sacrum; then extended on to the back and chest like any ordinary spinal brace.

Chronic Pancreatitis

DR. CHARLES N. SMITH, Toledo: Chronic pancreatitis presents two distinct pathologic and clinical pictures, depending on the location of the fibrosis. Thus we have the interlobular and the interacinar forms. In the first-named form, the islands of Langerhans are involved early, while in the last-named form they are involved late in the course of the disease. In the majority of instances the diagnosis of chronic pancreatitis is not impossible, nor is it difficult. In my experience, the Cammidge pancreatic reaction has proved a valuable and thoroughly reliable indication of the presence of pancreatic inflammation. As practically 80 per cent. of the cases of chronic pancreatitis occur as terminal and sequential events in gallstone disease, the relations between the common bile duct and the head of the pancreas, and between the common and the pancreatic ducts, as well as the methods of termination of these ducts in the duodenum, become of more than passing importance. Drainage of the biliary tract is the essential element in the cure of the pancreatitis and must be continued over a period sufficiently long to assure a decided abatement in, or disappearance of, the biliary infection. In mild cases temporary drainage is indicated. Such operations performed early are attended by a mortality of about 1 per cent.; performed late the mortality may reach 18.5 per cent. When the disease has been of long standing, permanent drainage is indicated, which is obtained by cholecystenterostomy. The intestinal

site for the anastomosis should be in the duodenum, whenever possible, in order that the bile may enter the intestine and become mixed with the pancreatic fluid near the outlet of the stomach, as was Nature's intention and provision.

DISCUSSION

DR. FRANK E. BUNTS, Cleveland: In two-thirds of all cases the common duct goes through the pancreas, while in one-third it goes under the pancreas, and the enlargement of the head of the pancreas pressing on the common duct accounts for the frequent occurrence of jaundice as a symptom of pancreatitis. In stone of the common duct, in a large percentage of cases, there is a small gall bladder with persistent jaundice, while a large gall bladder with persistent jaundice is in all probability due to a carcinomatous condition or to trouble in the pancreas. Of course, in obstruction of the cystic duct, there is enlarged gall bladder, but not ordinarily. Pancreatitis may be an accompaniment of alcoholism, syphilis or mumps, but it is usually then of an acute form, and not chronic, although in syphilis it may sometimes assume a chronic form.

DR. LEVISOHN: The Cammidge reaction is of value and the profession should have recourse to it more frequently.

DR. BROWN, Toledo: I worked with Dr. Smith in his effort to study surgical cases of chronic pancreatitis, associated with biliary disease. I made 93 urinary examinations from 39 different individuals suffering from various ailments. Of the 39 patients, 10 gave positive and 29 negative reactions to the Cammidge test. The positive reactions were obtained from 7 patients with gallstones, from one case of catarrhal duodenitis with occasional icterus, from one case of diabetes of pancreatic origin, and from one case of gastric ulcer with adhesions to the pancreas. Out of 17 cases of cholelithiasis 7 gave positive and 10 negative reactions. While my own observations have been limited, still the consistent results secured and their confirmation in 15 cases has convinced me that we have at our disposal one of the most valuable diagnostic aids that has recently been introduced into medicine. My experience in malignant conditions of the pancreas has been limited to two cases. In both the reaction was negative. Cammidge believes that the reaction in this condition is dependent on the presence or absence of any coexisting pancreatitis, which view is generally accepted.

DR. J. H. SCHROEDER, Cincinnati: The cases resolve themselves into two classes: One in which there is no jaundice, but digestive disturbances, and no symptoms of gall-bladder disease; and the other, in which there are jaundice and symptoms of gall-bladder disease. When Cammidge first published his reaction in 1904, I followed it closely, and presented an analysis of 85 cases at the Chicago Session of the American Medical Association meeting last year. When the reaction was positive, it was usually in connection with gall-bladder disease. I obtained the reaction in one case of intestinal influenza and in one case of measles, but there was no jaundice and tenderness over the pancreatic region and no gastric disturbance. As a whole, I think the test a valuable one, but not pathognomonic.

Interilio-Abdominal Amputation

DR. JOSEPH RANSOHOFF, Cincinnati: The patient in this case was a colored man, aged 45, who six years before his admission to the hospital, sustained a kick in the groin. Three years later an osteoma developed, which was removed. The patient returned to the hospital a year later with the wound opened and many sinuses leading to a tumor which involved the pan of the ilium and the upper end of the femur. The diagnosis of osteosarcoma was made. Although the patient was in a condition of chronic sepsis, an interilio-abdominal amputation was made March 8, 1900. Hemostasis was provided for by tying the common iliac artery. Owing to many sinuses on the outer side of the hip and gluteal regions, and the position of the tumor, a long internal flap operation was the only one feasible. The ilium was chiseled through from crest to sacrosciatic notch just in front of the synchondrosis, and the ramus of the pubes and ischium were chiseled through in the same way. At this time the fall of blood

pressure necessitated an intravenous injection. The operation was completed in forty-five minutes and the patient left the operating table in fair condition. With the varying symptoms of sepsis, the patient survived for thirty-nine days.

ASSOCIATION OF AMERICAN PHYSICIANS

Twenty-fourth Annual Meeting, held at Washington, D. C., May 11-12, 1909

(Continued from page 1781)

Clinical Experiments with Homologous Vaccines in Septic Endocarditis and Pyemia

DR. W. GILMAN THOMPSON, New York: Following the method described by Wright, I have treated a series of seven patients with septic (streptococcal) endocarditis and one with pyemia with results which have again demonstrated its effectiveness. Three of the patients with septic endocarditis were cured, also the one with serious pyemia. In several other cases of septic endocarditis there was clinical evidence that the septic process had been completely controlled, although subsequently death ensued from such complications as tuberculosis or pneumonia, which as yet are beyond the influence of vaccine treatment. In several of the cases, polyvalent vaccines were employed, but without benefit, before homologous vaccines could be obtained, which latter subsequently proved effective. In fact, in no case in which the homologous vaccines were used was there failure to produce some degree of reaction, such as a downward temperature movement, and other indications of at least temporary betterment, and several patients who came under treatment after months of illness in a condition in which a fatal issue seemed imminent, gave evidence of an arrested progress of the disease for many weeks. The three patients with endocarditis who recovered had a type of the disease in which I have never previously seen recovery take place. The dosage of the vaccines used varied between 50,000,000 and 300,000,000 at intervals of two, three or four days, according to the circumstances of the case. There is much yet to learn about the dosage and the intervals.

A Study of Achylia Gastrica

DR. CHARLES G. STOCKTON, Buffalo: Achylia gastrica is defined by Einhorn as "A class of cases in which there is permanent absence of gastric secretion," and "in which clinically the diagnosis of atrophy of the gastric mucosa seems to be justifiable." He does not include cases depending on pernicious anemia. Apparently, this definition describes a result following a variety of causes. Hence, we are led to conceive of the condition not as a disease, but as the result of diseases. If this be true, I fail to understand why the condition when occurring in pernicious anemia should not be included. I have attempted to state in this paper some conclusions reached in the study of 132 cases. Some of these did not fall strictly within the definition above given. If, however, we are to form an opinion as to the causes leading up to achylia gastrica and of cases in the stage of development, then these cases should be included. I believe that it is wise to include them and to attempt the explanation of a pathologic change that is not very uncommon.

DISCUSSION

DR. THEODORE JANEWAY, New York: Our knowledge of the anatomic changes associated with disturbances of gastric se-

cretion is very scant, because on account of the postmortem digestion which usually takes place the histologic examination of the stomach after death is attended with considerable difficulty. In the few cases of achylia gastrica which I have been fortunate enough to see come to autopsy, the presence of a true atrophic gastritis has been rather conspicuously absent. The two most striking groups of cases are those associated with pernicious anemia and those associated with certain types of persistent diarrhea. A number of persons coming especially from Cuba and South American countries have chronic diarrhea, and on careful examination they will be found to have achylia gastrica. These cases are the ones which offer most hope therapeutically. They respond admirably to the administration of hydrochloric acid.

Locomotor Ataxia and Paralysis Agitans in the Same Patient

DR. AUGUSTUS A. ESHNER, Philadelphia: Locomotor ataxia and paralysis agitans have little or nothing in common, etiologically, anatomico-pathologically or symptomatologically. Their associated occurrence in a given patient must, therefore, be looked on as a mere coincidence. While by no means rare, neither disease is common, and their association is correspondingly infrequent. Only a small number of cases have been placed on record in which both diseases have been present in the same patient. In my case, which occurred in an elderly man, the symptoms of paralysis agitans were observed while the patient was under treatment for locomotor ataxia, although members of the family stated that they had noted some shaking of the hands for many years.

Further Observations on the Third Heart Sound

DR. W. S. THAYER, Baltimore: During the past year I have examined 231 consecutive normal individuals in various places—schools, child's nursery, city jail, etc. In those individuals 65 per cent. under 40 years of age showed a characteristic third sound of greater or less intensity. In the first three decades of life the sound is the rule. It is apparently a normal sound in a large proportion of adolescents and young adults. Our studies rather tend to support the suggestion made by Dr. Hirschfelder, Dr. Gibson and myself independently that the sound is probably due to a slight tension of the mitral valves associated with the rapid filling of the ventricle. The sound is certainly coincident with the inrush of blood from the auricle into the ventricle. The diastolic gallop is present in the majority of individuals under 30, in the recumbent and left lateral postures, and is not, *per se*, a pathologic manifestation.

DISCUSSION

DR. JAMES L. WILSON, Philadelphia: Students of cardiac diseases must have been since the time of Laennec more or less incompetent as regards their hearing to have overlooked this sound until recently when our attention was called to it. In a considerable number of instances I have recognized the third sound under circumstances in which the possibility of my having overlooked it up until recently could scarcely have occurred. Of course, I have recognized the first element of the diastolic gallop rhythm very often, but while this occupied the time of the third sound as now observed, that this could under any circumstances have been a normal sound had never occurred to me. The subject is certainly one which deserves very systematic clinical investigation, and in which the correlation of the clinical observations and postmortem observations should be systematically made whenever practicable. The idea of the occurrence of a third sound of the heart under normal circumstances, after nearly a century of clinical study of the heart by physical diagnosis, comes with overwhelming force, and impresses on us the fact that we have to have things pointed out to us from day to day before we understand them.

Normal Auscultatory Differences Between the Sides of the Chest

DR. RICHARD C. CABOT, Boston: If we study the slightest auscultatory differences in different portions of the chest, we will have to recognize not merely that there is a difference

between the two apices, but very frequently a difference between the two bases. I recently went over 250 chests that were normal so far as I could find. In 64 per cent. of those cases there was a difference between the two bases, and substantially the same difference. At the left base behind the breathing in these 64 per cent. of cases was harsher, rougher and slightly louder than at the other base. It was almost exactly what the Germans call rough breathing, as compared with the smoother, gentler breathing at the other base. It is only of importance in that it should modify slightly what we otherwise might take as a pathologic sign in the same way that our attention to signs at the right apex always has to be slightly modified by our knowledge of the physiologic conditions there. The other point to which I wish to call attention is not new, but I am convinced sufficient attention has not been paid to it. We have all of us known for a long time that it is unwise to examine patients in the lateral posture, because the sounds of the two sides of the chest are modified very much by the lateral decubitus. In 50 chests which I examined, the results were practically identical and precisely what we should suppose from the physical conditions. Lying on the side diminishes the excursions of that side of the chest and increases the density of the lung. On palpation we get a slightly increased fremitus; percussion shows a slight dullness combined with tympany; on auscultation we get a slight increase of the whispered and spoken voice, a slight prolongation of expiration and a slight increase in its intensity.

DISCUSSION

DR. W. S. THAYER, Baltimore: In a good many cases, particularly in febrile diseases, one hears numerous crisp râles on the recumbent side of the chest, while on the side of the chest which is up there are no similar sounds. If the patient is changed from side to side the râles entirely disappear, and not infrequently appear on the other side of the chest. It is familiar enough to most of us that fine, crisp râles occur with the expansion of the thin borders of the lung in various parts of the chest. I have not infrequently seen the attention of clinicians attracted to râles which were heard in the axilla. If the individual is lying on his back and turns on one side the râles will entirely disappear in a large proportion of cases. If we percuss the lung at the same time, we will find that it has come down two or three fingers' breadth, and with the filling up of that portion of the lungs the râles disappear. I know of at least one patient who was sent to the mountains with a diagnosis of tuberculosis based solely on a manifestation which is really not abnormal nor uncommon.

Orthodiagraphy in the Study of the Heart and Great Vessels

DRS. THOMAS A. CLAYTOR and WALTER H. MERRILL, Washington, D. C.: From our experience with the orthodiagraph we draw the following conclusions: While orthodiagraphy should not be looked on in any way as a substitute for the other well-known methods of examination of the heart and great vessels, it is, at the same time, a valuable aid. It can be used to make fairly accurate outlines and measurements of the heart and great vessels, thus enabling us to make comparisons with the normal and subsequent diagrams of the same case. The use of the instrument may also serve to prove that the size of the heart is not influenced to any appreciable degree by a single effort of exertion, or by a single therapeutic or gymnastic treatment.

(To be continued)

MISSISSIPPI STATE MEDICAL SOCIETY

Forty-second Annual Meeting, held at Jackson, April 13, 1909
(Concluded from page 1639)

Errors of Refraction and Results to Be Expected from Their Correction

DR. W. S. SIMS, Jackson, maintained that the fitting of glasses should not be left to the optician or to the optometrist. In young subjects the work should be done with the eyes under the influence of some reliable cycloplegic. Glasses

would be found beneficial in reviewing poor vision, headaches, certain forms of conjunctivitis, vertigo and nausea after long use of the eyes, but of little or no benefit in migraine, chorea or epilepsy.

DISCUSSION

DR. H. FLOWERS, Brookhaven: Though the general practitioner is not expected to understand the various complications of the eye, he should know more than he does on the subject, and should at least warn his patients against the opticians who call themselves doctors. They know nothing about the eye, do not use atropin, and can not refract. They frequently put glasses on people whom a specialist would relieve by treatment. Again, they put glasses on which positively injure the eye. Therefore, the general practitioner would do a great deal of good by advising his patient against these opticians, and referring them to some competent specialist, if it is a trouble he can not treat himself.

DR. WILLIAMS: When the eyes are constantly breaking out with styes, the lids become inflamed, and the patient complains of burning of the lids and watery eyes, it is safe to say that that patient has an error of refraction, and if that error is properly corrected, good results will follow. When the general practitioner sees these cases, he should advise his patient to go to a specialist and have this trouble corrected at once.

DR. E. A. CLARK, Arcola: In small places opticians are particularly annoying. I have had some very disagreeable experiences with them, and think that physicians should warn their patients against them.

DR. TURNER: After I left college it did not take me long to find out that I did not know anything about the eye, and I am still of that opinion. I made it a point to send my patients to a reliable specialist when I discovered anything wrong with the eyes. I have had a number of disagreeable experiences with men who called themselves "Doctor." One came to my town and tried to prevail on my clerk to buy his outfit, promising him that he would stay there two weeks, and at the end of that time, he would have made a first-class oculist out of him. I cite this case to show how necessary it is to put a stop to these men going about misrepresenting facts, and doing a lot of harm.

DR. HAMILTON, Schlater: I wish to call attention to the reflex nervous symptoms from strain of the ciliary muscle, causing headache and nausea. This can frequently be relieved by wearing glasses, but I believe that a great many cases of eyestrain can be relieved by a dose of calomel.

The Relation of the Specialist to the General Physician

DR. D. G. MOHLER, Gulfport, contended that the specialist should limit his work strictly. He must observe ethics and never lose sight of the rights of the general physician. The specialist and general physician should work in harmony in all cases and can give each other great help in the diagnosis and treatment of many obscure cases.

DISCUSSION

DR. W. B. DOBSON, Jackson: The general practitioner and the specialist should work together for the best interests of their patients. I have heard some general practitioners say that they felt perfectly competent to treat the eye, and why should they send their patients away when they could treat them. When the specialist discovers that his patient is suffering from some physical trouble, not in his line, he sends him to his family physician for treatment, then why should not the general practitioner give the specialist the same courtesy. The best interest of the patient can only be obtained in that way. In twenty-five years from now we will see the general practitioner only in small towns and villages; each physician will be a specialist along some line, such as lungs, stomach, eye, etc.

DR. M. ALEXANDER, Tunica: Most cases of eye troubles came under the notice of the general practitioner first, and he should know whether he is able to treat those cases or not. If he feels that he can not treat a patient successfully he should send him to a specialist.

DR. J. A. ROWAN, Wesson: No man is competent to be a specialist, unless he has first been a general practitioner. He should certainly have a general knowledge of the practice of medicine. I desire to endorse what Dr. Hamilton said in regard to a dose of calomel helping the vision in some cases. When one is bilious the sight certainly becomes dimmer, and a dose of calomel will certainly clear the vision in these cases.

DR. J. T. H. POSEY, Enterprise: Recently a physician referred to himself as being loaded with junk, and I want to say that this junk is very necessary to the country physician who is miles away from a city, and who certainly should know something about treating the eye. Most country patients are not able to go to a specialist; and in simple eye trouble the physician should know what to do for his patient. He should also know when he meets an eye trouble that he does not understand.

A Plea for the Proper Treatment of the Cross-Eyed Child

DR. M. H. BELL, Vicksburg, said that speaking only of esotropia, glasses should be fitted as early as possible and treatment should not be delayed trusting that the patient will outgrow the trouble or while waiting to have an operation done later. The family physician is the one who sees these cases at a time when proper treatment offers much hope and he should give them more attention.

DISCUSSION

DR. H. FLOWERS, Brookhaven: When a child squints it is very unwise to wait until that child is 6 or 7 years of age to correct the squint. I consider it most important to see that that child uses both eyes. When a child only sees with one eye, by the time it has reached the age of 6 or 7 years it will have lost the vision in the eye it did not use. To force the child to use both eyes, the eye the child uses should be rendered useless with atropin, and it will have to use the other eye. An examination should be made every few weeks, and the child should be kept using first one eye and then the other. It is not usually satisfactory to put glasses on a child 2 or 3 years of age, but it can be done if necessary.

DR. WILLIAMS, Jackson: I do not agree with Dr. Flower in regard to the child with the alternating squint. I think that such a child should have attention at once. Glasses can even be tied on. The general practitioner should not lose sight of this fact, as they are looked to for advice on these matters, and they should tell parents that this condition can be relieved, and at once, and thus save a child from going through life with one eye looking in one direction and the other looking in another direction. By urging on the parents the necessity of having this trouble attended to at once, the general practitioner can do an enormous amount of good.

DR. KENNEDY: My experience has been that glasses are of very little advantage. In my youth I was very cross-eyed and glasses were tried. I stood them as long as I could, but they caused me such suffering they had to be discarded. In after years, when I began the study of medicine, I gave this trouble close attention and again tried glasses, without success. Finally, I went to Memphis, where an operation was performed, but I was then too old for it to do much good; it relieved me, however, and put me in condition where I could wear glasses. Therefore, I would recommend that a child be operated on at once.

DR. BRISTER, Greenwood: What does Dr. Bell consider the best age to operate on a child?

DR. BELL: It is my practice to let the other man do the operating. In reply to Dr. Kennedy, I would say that I do not think he will find many specialists who would operate without first treating with glasses.

Quinin Amaurosis

DR. J. B. ELLIOTT, JR., New Orleans, reported two cases of quinin amaurosis. In the first 690 grains had been given in ten days, part by needle and part by mouth, and in the second 410 grains in eight days. These were contrasted with a case of pernicious malaria controlled by 280 grains in eight days.

The object in presenting the cases, as stated by the author, was to bring up a discussion as to the frequency of quinin amaurosis and more especially to get the views of the members of the association as to the maximum dose of quinin to be used in pernicious malaria.

DISCUSSION

DR. H. L. SUTHERLAND, Rosedale: I have lived in a malarial district for thirty-six years and have never had a case of quinin amaurosis. This is probably due to the fact that I do not advocate giving such heroic doses of quinin in malaria; I see no use in giving such enormous doses. I can accomplish just as much good by giving from 20 to 30 grains a day to the average adult. In lobar pneumonia, I have given 60 grains in a space of ten hours, and repeated the dose in twenty-four hours, and also have given doses of that size in some forms of puerperal fever, but not in malaria. I have never seen a case of malarial fever that 30 grains of quinin daily, for four days, would not cure, but I never gave it more than four days in succession, for if the fever still continued, I looked around for another diagnosis.

DR. FRIZELL: Does Dr. Elliott give quinin by enema or by needle?

DR. LONGINO: What solution is necessary to saturate the blood and kill the more persistent parasites?

DR. ELLIOTT: I give the quinin by the needle. Administered by mouth and through the bowels it is not always absorbed. In a case of a man on whom a postmortem examination was made, forty-eight 5 gr. pills were found in the bowels. That man died with his bowels full of quinin and his blood empty of quinin. A solution of 1 to 5000 will destroy persistent parasites.

Uncinariasis and Its Relation to State Medicine

DR. J. A. MCCOY, Picayune, discussed the prevalence of uncinariasis in south Mississippi. The disease was much more common than was generally supposed. He described two cases he had seen that terminated fatally on account of complications—the second, a girl of 8 who had developed an abnormal appetite, going to autopsy. There was found in the stomach a matted mass of human hair. He summarized his article as follows: "Uncinariasis is the most prevalent chronic disease existing in south Mississippi; it retards mental and physical development of all affected persons; it is a curable disease, also preventable; it exists principally among the poorer people of rural districts who are not able to pay for treatment, therefore the state should provide means whereby it may be eradicated."

A State Bacteriologic Laboratory

DR. W. S. LEATHERS, University, described the uses of a state bacteriologic or hygienic laboratory and considered the reasons why the physicians of Mississippi have failed so pitifully in their efforts to secure legislation.

What Bacteriology Has Done for Medicine and Some of the Handicaps to Its Study

DR. G. H. WOOD, Batesville, enumerated some of the benefits conferred on medicine by bacteriology, advocated the necessity for a public, state laboratory and blamed the medical fraternity for the absence of one in Mississippi.

Discussion on Bacteriologic Laboratory

DR. S. L. BRISTER, Greenwood: Though I am not a bacteriologist I fully appreciate the benefits the general practitioner derives from bacteriology. In any tuberculous trouble the bacteriologist comes to the assistance of the physician most materially. I am in favor of some effort being made to get the legislature to make an appropriation sufficient to establish a state laboratory in Mississippi.

DR. W. STEPHENSON, Lauderdale: Every effort should be made to secure a state laboratory, but while waiting for this laboratory I wish to call attention to what is being done in east Mississippi. Through the activity of Dr. Buchanan the

physicians there have obtained an appropriation from the legislature to build and equip a modern laboratory. It is large, and has every convenience for making examinations. They intend to get out a little book on the subject of how to send specimens, how to prepare specimens of blood, and how to preserve specimens for examination.

DR. J. B. BULLITT, University: Every effort should be made to establish a state laboratory, but the physicians should also be fitted to make examinations himself. The majority of physicians do not know how to make the simplest examinations. They would then acquire a deeper interest in securing a state laboratory. It is astonishing how careless many physicians are in sending specimens to be examined. Some wrap the tissue to be examined, in a piece of paper, stuff it in the pocket, and in the course of time send it on to be examined; or they drop the blood on the center of the slide, and then stir it up, and are much astonished when the bacteriologist sends word that it is impossible to make an examination of the specimen sent. The establishment of a laboratory would at least enable the physician to learn how to send the specimens to be examined, even if he never attempts to make an examination himself.

DR. H. L. SUTHERLAND, Rosedale: It is necessary to make some effort to get the legislature to pass an act authorizing the establishment of a state laboratory, but to do so it is necessary to have literature for distribution among the legislators, and such papers as these that have been read should be printed in such form as to distribute to the legislators when they next meet in Jackson.

DR. S. W. SCALES, Starkville: With a microscope and a simple course of study, the physician would soon learn to make a few examinations for himself. I am glad that Dr. Stephenson has called attention to the work being done in Meridian.

he Prevalence, Prophylaxis and Economic Importance of Tuberculosis

DR. J. M. ALFORD, Ellisville, considered tuberculosis from the standpoint of its prevalence, prophylaxis and economic importance. The scourge was everywhere, it might be prevented and ultimately eradicated. Its cost to the community and nation, both in loss of lives that had an economic value and in cost of caring for tubercular invalids, was exceedingly great.

DISCUSSION

DR. H. L. SUTHERLAND, Rosedale: This plan of educating the people on the prevention of a disease, which is known to be preventable, is necessary. There is a law requiring a physician to report all these cases to the state board of health, and the physician who fails to do so commits a great wrong. Though something of a pessimist in regard to the treating of tuberculosis in the negro, in one instance I treated successfully a tuberculous negro—a very intelligent negro boy. At first I thought of sending him to New Mexico. I gave him a copy of the *Mississippi Medical Journal*, containing an article on tuberculosis and told him to read it carefully and to follow out the line of treatment laid down in it. He was then having high temperature, night sweats, and cough. He persisted in the diet of sweet milk, raw eggs, etc., combined with perfect rest and sleeping outdoors. The results were better than I could have expected. When I saw this man in October, had I not known the history of his case, I would have passed him for life insurance. If the people could only be reached with such literature as that article, instead of all this "patent-medicine" literature, while it might result in no good to some, it might be the means of saving the lives of a good many.

DR. ROSAMOND, Memphis, Tenn.: I think it is time that the physician recognized the importance of being able to diagnose tuberculosis in its incipency. I also think that the time is coming when it will be required that every child should be inoculated with tuberculin. Everyone should learn more about tuberculin and its possibilities and more about the exact diagnosis of incipient tuberculosis, and when they do this they will strike at the root of the trouble.

DR. J. ROWAN, Wesson: Every disease that is stamped out is stamped out by isolation—yellow fever, smallpox, diph-

theria, etc. How can tuberculosis be stamped out otherwise? And this can only be done by prohibiting the marriage of consumptives.

DR. JONES: The people of the South suffer through tuberculosis in the negro more than do the northern cities. It is no uncommon thing for negro nurses, employed by society people, to be sent to be treated for tuberculosis while holding little white children in their arms. It behooves the South to direct particular attention to this class of consumptives and to protect its little children from such a menace.

DR. HOLDER, Memphis, Tenn.: One form of tuberculosis that has not been discussed is tuberculosis of the bones and joints. The little child will complain of pains in its knees and the mother will think that it has growing pains. He will begin to limp and to cry out in his sleep, and there is just a little rigidity of the muscles of the thigh, and that child will develop tuberculosis of the hip joint. If this trouble can be diagnosed in time, the pressure taken off, the child given the proper diet, plenty of outdoor air and moderate exercise, he may get well. Let it alone until the second and third stages, no power on earth can save bones and joints from total destruction. The treatment of tuberculosis of the joints and bones is the same as tuberculosis of the lungs. We do not contract this disease in the day time; it is in the darkness of the night, shut up in ill-ventilated rooms. A law should be passed appointing health inspectors of all public buildings, theaters, churches and all public places, and every private house should have an open-air chamber, where the child should sleep. People should not wait until they have tuberculosis to begin to fight it, but prevent it by living sensibly.

DR. J. M. ALFORD: The question of legal prohibition of the intermarrying of consumptives is a very serious one. If the trouble is diagnosed in its incipient stage, there is no need of such a prohibition. But who shall say at what stage it shall stop? I do not think that it would be wise legally to prohibit the individual with incipient tuberculosis from marrying.

The following papers were also read: "Some Valuable Medicinal Agents in Diseases of Women," by Dr. W. A. Carnes, Kosciusko; "Some Neglected Gynecologic Disorders," by L. C. Feemster, Nettleton; "Report of a Case of Extrauterine Pregnancy," by Dr. J. C. Armstrong, Water Valley; "Some of the Nervous and Mental Arrangements of Alcoholics," by Dr. J. A. Tullos, Raleigh; "Hereditary Syphilis as an Etiologic factor in Dementia Præcox," by Dr. M. J. Ferguson, Jackson; "The Prophylaxis of Insanity," by Dr. J. M. Buchanan, Meridian; "Disturbances of the Organs of Generation as a Causative Factor in Insanity," by Dr. A. E. Kennedy, Magee; "Criminal Irresponsibility," by Dr. E. L. Green, Carpenter; "The Diagnosis of Labor," by Dr. A. L. Chapman, Lyon; "Electricity as a Therapeutic Agent in Gynecology," by Dr. Rosa Wiss, Meridian; "Typhoid Fever in Infancy and Childhood, with Analysis of Eighty Cases," by Dr. W. W. Butterworth, New Orleans; "Our Hygienic Duty," by Dr. C. S. Pettus, El Dorado, Ark.

ILLINOIS STATE MEDICAL SOCIETY

Fifty-Ninth Annual Meeting, Held at Quincy, May 18-20, 1909

The President, DR. J. W. PETTIT, Ottawa, in the Chair

An address of welcome was delivered by Dr. R. J. Christie, Quincy, which was responded to by President Pettit.

Serum Treatment of Epidemic Cerebrospinal Meningitis

DR. FRANK SPOONER CHURCHILL, Chicago: I have been able to watch the effect of the serum in 41 cases of meningitis, 29 of which were proved to be of the meningococcic type. Of these 29 patients, 16 recovered, 13 died, a mortality of 44 per cent. Closer analysis of the series showed that of 15 patients receiving the serum within the first week, 6, or 37 per cent., died. Of these 6 cases, 3 were fulminating cases, and the patient died within the first two days. The fourth patient was a baby, tender, aged 43, and the other two were not closely followed up,

but received each only one dose of the serum. The following conclusions were reached: 1. In all cases clinically suggesting meningitis, a lumbar puncture should be done as early as possible. 2. If the fluid thus obtained be turbid, at least 30 c.c. of Flexner's serum should be injected directly into the spinal canal without waiting to hear the bacteriologic report of the fluid. 3. The spinal fluid should be examined bacteriologically. Smears are more important than cultures. If the diplococcus intracellularis be found, the injections should be repeated daily for the three or four following days. In severe cases the second dose should be given twelve hours after the first. 4. After the first series of doses, two or three days should be allowed to elapse, and then, if necessary, the series repeated. 5. The serum is a specific and of value in meningococcic meningitis only. 6. It is useless to give the serum subcutaneously.

DISCUSSION.

DR. S. E. MEXSON, Springfield: Through the courtesy of Dr. Churchill, I had the privilege of using the Flexner serum in two or three cases of cerebro-spinal meningitis. One of the patients was moribund at the time the serum was injected, and died within an hour or two afterward. I speak of this as being a case of cerebro-spinal meningitis owing to the character of the spinal fluid and the differential cell count, particularly as to turbidity, etc. A second case I saw with another physician who had called me to administer the serum, and it was clear from the history of the case that it was one of tuberculous meningitis, and on spinal puncture the fluid was perfectly clear. After the serum had been used for some twelve hours a fine coagulum was found, and on removing fluid and staining for tubercle bacilli, they were found in numerous quantities. A third case was one of cerebro-spinal meningitis. This patient received the serum at about 3 o'clock in the afternoon of the fifth day of the disease, and about midnight the temperature became normal, with profuse sweating, and after that time there was no rise in temperature. This patient, a child, rapidly improved, and in six weeks' time returned to school again, having fully recovered. It was as severe a type of fulminating cerebro-spinal meningitis as I have ever observed.

DR. FRANK BILLINGS, Chicago: Anyone who has seen these meningitis patients treated by old methods, as, for instance, by drugs or hygienic means alone, will be struck with the specificity of this treatment when they have had some experience with it. I want to relate briefly two cases to show how quickly the disease manifests itself. A little over a year ago a Greek, between 20 and 30 years of age, was brought in from South Chicago. He was so nearly unconscious that he recognized nothing. He was unable to speak English, but manifested the site of pain by placing his hand at his head. His muscles were all rigid. There was opisthotonos. Spinal puncture was made and turbid fluid obtained, which showed the meningococcus. Serum was immediately injected, and within twelve hours of that time this young man sat up in bed, and indicated by his motions that pain was gone. The muscles were less rigid. He was given subsequent injections and steadily improved until recovery ensued. A patient now in the Presbyterian Hospital, Chicago, a man of 26, twenty-four hours before admission, was taken with violent headache. When brought in he was semiconscious; his muscles were rigid; his head retracted; his belly scaphoid, and the right external rectus muscle paralyzed. Immediately spinal puncture was made and some fluid obtained. No serum was on hand at the time, but that night 30 c.c. were injected. His symptoms were not much relieved by morning, and again a second spinal puncture was made, and over 30 c.c. of spinal fluid was withdrawn. The next day, again, about 40 c.c. of fluid were withdrawn from the spinal cord, and 45 c.c. of serum injected. By this time the man showed great improvement. Paralysis of the right external rectus had diminished very much. He was conscious; he spoke in broken English, and expressed himself as feeling better. He still had some headache and stiffness of the muscles of the neck. Since that time he has had injections every five days. After the last injection his temperature was most normal, and found to be 99 F., and pulse below 90. His respirations were normal. Still he showed rigidity of the neck muscles, and some rigidity of the erector spinae muscles, and

rigidity of the hamstring muscles is still present. Otherwise he seems to be much better. The remarkable thing was the effect of the leucocytes in the blood and in the spinal canal. When he entered the hospital, his white blood count was 23,000. After the first injection it fell to 2,000. By the next day it went to 32,000, and then fell steadily. The spinal canal fluid contained 13,000 plus white cells per cubic millimeter when he came in. This patient will undoubtedly make a good recovery.

DR. JOHN M. DODSON, Chicago: I believe we shall do better, in the present status of the serum, if we establish the diagnosis before we make an injection of the serum. I am not at all certain that the use of the serum is absolutely unattended with unpleasant results. In one of the cases cited by Dr. Billings, after one or two injections, a skin eruption was noticed. In one case last autumn one of my assistants injected the Flexner serum in a case of tuberculous meningitis, and the injection was followed by a distinct intensification of the symptoms.

The Surgical Treatment of Appendicitis

DR. CLIFFORD U. COLLINS, Peoria: 1. The best time to remove an inflamed appendix is during the first thirty-six hours of the attack, before it becomes perforated. 2. The physician who does not see or hear from his patient for twenty-four hours after his first visit in a case of suspected appendicitis is not doing his full duty to his patient. 3. After the appendix has become perforated, the patient will do better if its removal is deferred and he is placed on his right side with the head of the bed elevated and treated according to the principles of the Ochsner treatment, with the Murphy method of continuous rectal saline infusion. 4. After the appendicitis or the succeeding peritonitis has subsided, the appendix may then be removed more safely. 5. If a localized abscess forms, the pus should be evacuated under nitrous-oxid-gas anesthesia. 6. As soon thereafter as the pulse and temperature have remained normal for one week the appendix may be safely removed.

DISCUSSION.

DR. A. J. OCHSNER, Chicago: The most important point in the surgical treatment of appendicitis is the diagnosis. It is inexcusable to leave a patient, who has an acute intra-abdominal condition, without a diagnosis having been made for twenty-four hours, we will say, to give him something for the pain, and then make the diagnosis the next day. I believe that that is the primary cause of the still high mortality in the treatment of this disease. If a patient receives a careful physical examination at first, then it is likely that this examination will result in a positive diagnosis provided an acute appendicitis is present. If this is not possible, nothing should be given that may interfere with making the diagnosis. I agree that opiates should never be given, and that if anything is given at all, it should be in the form of a placebo until the diagnosis is made. Opium should never be given to a patient suffering from any intra-abdominal condition until the diagnosis has been made and until gastric lavage has been resorted to. After the diagnosis has been made, treatment should be instituted.

DR. CHRISTOPHER GRAHAM, Rochester, Minn.: If a patient presents himself early and a diagnosis of appendicitis is made, the appendix should be taken out early, and that is the practice of St. Mary's Hospital, Rochester. This country is full of surgeons of two classes. To the one class it is safe and sound to send our patients. Then there are others, called surgeons, whose judgment is not so ripe and whose skill is not so great. There is much in the judgment of the physician or surgeon as to when the operation should be done.

DR. JOHN B. DEEVER, Philadelphia: I believe in the early application of the scalpel in the treatment of appendicitis. Opium and salts should be relegated to the past. They have no place in the modern treatment of appendicitis. McBurney pointed out a number of years ago that there was but one treatment for appendicitis—the knife, and I can only iterate the statement of that magnificent man, that pathfinder.

DR. CARL E. BLACK, Jacksonville: In the country we have to contend with the timidity which still exists among general practitioners. We must try to overcome this. General prac-

tioners still wait and wait to find out what is the matter when they ought to know the true nature of the case in a short time. The crux of the whole matter consists of early and prompt diagnosis and early operation.

Dr. M. L. HARRIS, Chicago: One of the most pernicious practices which is prevalent to-day is the administration of cathartics. A patient with a pain in the belly should never under any circumstances be given a cathartic of any kind or description until it is absolutely certain that he or she, as the case may be, is not suffering from appendicitis or from any other intra-abdominal condition which is going to produce or may produce a peritonitis. Another most pernicious teaching which has been promulgated is an attempt to divide cases of appendicitis into those of so many hours and so many days. There is no condition in the abdomen which is so variable in its manifestations as that of appendicitis. I have seen a patient with appendicitis die within twelve hours from the first symptom. Another patient may go from ten to twelve days without serious symptoms being present. There is no such a thing as being able to divide cases of appendicitis into twenty-four or thirty-six hours, or three or five days. There is no trouble in telling what to do in appendicitis in those cases that are distinct and unmistakable. When the diagnosis is clear, operate. The question of abscess formation does not enter into consideration. If there is an acute appendicitis, get at the appendix if you can before the infection has extended beyond the appendix. If you can not get it out at once, do so just as soon as you have an opportunity.

Dr. FRANK BILLINGS, Chicago: Diagnosis is important. It is up to the surgeon to say when to operate after a diagnosis has been made. One phase of the disease is seen by medical men alone, namely, general conditions that are produced by chronic appendicitis. I thoroughly agree with Dr. Graham that an appendix which interferes with digestion with the constant absorption due to the disturbed metabolism produces general changes of a degenerative nature; hence the reason for removing the local infecting point and saving the patient from the chronic changes. I recall the case of a patient, a man of 55, who had chronic appendicitis with severe angina pectoris. He was greatly improved, and had no further attacks after the removal of the appendix. There was more than an immediate reason for the removal of the appendix.

The Value of Diabetic and Prepared Foods

Dr. R. T. WOODYATT, Chicago: The objects for which prepared foods are theoretically intended are the nutrition of those who for some reason are handicapped in their power to get sustenance from foods ordinarily available. The selection of a prepared food depends on the nature of the case. The fundamental requirements, which a suitable food must fulfill and on which any individual foods are to be judged are its content of matters capable of yielding energy in the body—fuel value; its digestibility; its availability, which includes steady market supply and price. The prepared foods now on the market are considered specifically in accordance with the foregoing principles under two main groups, namely, convalescent, invalid and infant foods, and diabetic foods. The essence of dietetic treatment in diabetes, save in very severe cases, is the limitation of carbohydrate food. The craving for bread based on the cry of the tissues for sugar is best ameliorated by improving the tolerance of the body for sugars. Breads which satisfy this craving contain starch. Bread without starch is a paradox. The legitimate uses to which substitutes for bread may be put are the supply of a vehicle on which bread, cheese, etc., may be spread and which "bites" like bread; the supply of a greater variety of forms in which a patient may take his non-carbohydrate fare. There is a great tendency among physicians to prescribe gluten flours *ad libitum*. Free use of all except a very few diabetic flours leads to a high aggregate of starch ingestion *per diem* at high price and in spite of restrictions on the use of the common amylaceous foods.

DISCUSSION.

Dr. JAMES R. HERRICK, Chicago: I think all of us are inclined to be more or less careless in paying attention to the

proper diet for adults, and while many illnesses do not need very careful and strict attention to diet, general directions being sufficient, all of us make mistakes in not being explicit in telling patients what to eat and what not to eat, and we all err, I think, if not in prescribing, at least in allowing to be prescribed or to be used many of these so-called prepared foods without knowing their nutrient value. Many of these foods are not what they are claimed to be, and when we think we are giving patients nourishing food we are perhaps giving little better than nothing. In diabetes the diet is all-important. The more one sees of this disease, the more he feels that there is a certain group of cases in which, in spite of the utmost care as to diet, fatal results will follow.

Dr. ARTHUR R. ELLIOTT, Chicago: It is hard to kill a therapeutic fallacy once it has become established in the minds of the profession, and nowhere is this more emphatically demonstrated than in the fallacy of diabetic foods, this fallacy persisting in spite of the emphasis and the repetition with which the fraud of the so-called gluten breads has been shown by chemical analyses. The mistakes made in the care of the diabetic by many physicians are the administration of specific medication and the employment of gluten flours. Seldom does the internist see a case of diabetes that has not been permitted the use of gluten bread without any specific restriction as to the quantity. The objection to gluten bread does not consist so much in the fact that it contains carbohydrates, because every diabetic must receive a certain amount of carbohydrates. The error in giving gluten flour is that its administration is not restricted, so that we know how much carbohydrate the patient is securing. A much better end can be secured by employing honest bakers' bread, the carbohydrate content of which we know, and the quantity of which we can restrict within certain definite boundaries.

Dr. FRANK BILLINGS, Chicago: I am glad that Dr. Woodyatt has shown us the absence of food value from many of the liquid beef extracts. I wish he had gone on and shown us something of the want of value of the ordinary beef, chicken, veal and other broths so commonly used in the sickroom. Nearly twenty years ago, Fothergill called attention to the fact that by chemical analysis the ordinary beef extract as used at that time in the sickroom was nothing more than concentrated urine. It had no nutritive food value whatever. The fact of the matter is that these things have less food value than some urine. Diabetic urine would be far better food than many of these extracts. Not only that, but these extracts are frequently poisonous. How many times do we find in the sickroom beef extracts used in conditions in which the excretory organs of the individuals are not throwing out their own waste, and we are increasing the purin bodies in the bodies of those individuals by the use of such things.

Dr. FRANK S. CHURCHILL, Chicago: So far as the feeding of babies is concerned, we have learned to be accurate in this matter, and all the extracts that have been referred to by Dr. Woodyatt have been thrown out of the window. We rely on taking a milk which we know is as clean as possible, and with that milk prepare a food for the individual baby adapted to its digestive powers so far as fat digestive capacity, sugar digestive capacity, and proteid digestive capacity are concerned.

Dr. CHARLES S. WILLIAMSON, Chicago: I wish to emphasize the point that the various extractives have slight nutritive value. Not only are some of them worthless, but they are exceedingly toxic, as demonstrated by experiments. They have injurious effects, both on the cardiovascular system and heart, and these are points which should not be lost sight of in considering the acute infections.

The Responsibility of the State in the Care of the Mentally Deficient and Insane Dependents

Dr. FRANK BILLINGS, Chicago: This paper deals with a statement of the condition of the mentally deficient and insane dependents in the state hospitals for the insane, the feeble-minded, and in the various county almshouses. An attempt is made to show that the true economy in the care of these patients may mean, in the beginning, the expenditure of a greater amount of money, but that the final result will be saving to the state. Physicians have much responsibility

these matters, especially in the recognition of deficient mental states and of acute insanity and the proper method of managing this class of people.

Early Pulmonary Tuberculosis Treated by Different Tuberculins

DR. E. H. BUTTERFIELD, Ottawa: Tubercle bacilli of the human and of the bovine types have been identified in man. The bovine type is more common in children than in adults. I report briefly a series of 23 cases of early phthisis in which the bovine tuberculin was administered. The other series comprises 8 incipient cases in which Koch's bacillus emulsion was administered, and 17 incipient cases in which tuberculin was not used. My conclusions are: 1. In view of the results obtained in this series of cases and from observation of cases now under treatment, I am convinced that a tuberculin prepared from bovine sources has a marked and healing effect in tuberculosis of the lungs. Experience teaches that there is frequently a marked disproportion between the physical signs and the general condition of the patient. Many with slight activity of the tuberculous process and with slight lesions, in the presence of other virulent micro-organisms, have been forced to an irresistible decline. These are not suitable cases for the administration of tuberculin, and although there is some uncertainty in the action of the autogenetic vaccines, the desperate character of the cases to which these are given is a justification for their employment. 2. If the patient's natural resistance to tuberculosis is lowered, efforts must be made to improve this condition by complete rest, nutritious food and pure air. Tuberculin will not help if these potent agents fail. 3. The tuberculous infection must be limited either to one lobe of a lung or two small areas in both lungs. If cavities have occurred, and general constitutional involvement has taken place, tuberculin has little or no lasting effect. 4. The age of the patient must be considered. The younger the patient, the more readily does he or she respond to the action of tuberculin.

Cutaneous Reactions of Tuberculin

DR. FREDERICK TICE, Chicago: The tests employed were: (1) Scarification, vaccination, or cutaneous method of v. Pirquet; (2) the ointment or percutaneous method of Moro; (3) the dermo reaction method of Lignieres; (4) the differential scarification method of Detre for diagnosis and therapy. Some one or more of these tests were employed in 235 cases. Based on the observations in these cases the following conclusions appear justifiable: 1. Tuberculin as a means of diagnosis is a most valuable agent, but must be considered only from the standpoint of corroborative evidence. A positive reaction to tuberculin indicates the presence of a tuberculosis, but physical findings and symptoms must be considered, for a tuberculosis may exist and fail to give a reaction. 2. The cutaneous tests are to be preferred to the subcutaneous or the ocular methods, as there are no associated dangers or undesirable results. 3. The percutaneous method of Moro, for certain reasons, seems to be preferable. It is easily applied without objection on the part of the patient or relatives. This is not the case with the v. Pirquet test owing to the general antipathy to any form of vaccination and as the test in children is not infrequently associated with excitement and crying. The results are quite as constant and when a difference occurs it is in favor of the ointment. The dermo test is not so reliable and this may be due to the difficulty in applying as compared to the ointment, as the upper layer of the epidermis forms in rolls. 4. The more youthful the patient, the more valuable the test. When autopsy records are examined, with the view of determining the frequency of some form of tuberculosis, practically present in all adults, the unimportance of a positive test, without other findings become evident. A negative test in the adult, all circumstances considered, is more valuable than a positive one. The non-value of the scarification in the adult has been pointed out by v. Pirquet, v. Emmerich and Hamburger. 5. The type of the reaction bears no relation to the type of the disease. It is true, however, that the slowly developing mild reaction occurred in the apparently arrested, cured or old cases. The most active reactions took place in the surgical forms of tuberculosis. 6. Concerning the Detre reaction, the number of cases examined is not sufficient for conclusions, but it would appear

that much information is to be obtained by such a test. The frequency of the old tuberculin producing the dominant reaction would indicate that, therapeutically, one of the filtrates or a combination should be employed.

Discussion on Tuberculosis

DR. S. E. MUNSON, Springfield: Nine years ago I read a paper in regard to bovine tuberculosis as affecting the milk supply, and at that time there was scarcely enough evidence to show that bovine tuberculosis is transmissible to the human being. After reading that paper, I corresponded with men of wide experience and observation, and among them with Professor Holt, of New York, who wrote me that he did not believe bovine tuberculosis was transmissible to the human being. There were many physicians, however, who believed that it was transmissible, and I am glad to know to-day that the opinion prevails among those who have had opportunity to investigate that it is communicable from cattle to human beings. I think the source of our milk supply in each community rests largely on physicians, and it is certainly of great importance to the medical profession in their work and in the care of their families that they know something about the milk supply children are fed on.

DR. E. F. INGALLS, Chicago: Remembering that practically every adult has tuberculosis or has had it, it is very important that we should be able to make a diagnosis of active tuberculosis as soon as possible, and, it seems to me, the statement of Dr. Tice is conclusive of the fact that these cutaneous tests are of value in determining whether or not the case is active. Perhaps we can not prove it, but taken in connection with the other means of making a diagnosis the cutaneous test is of much value.

DR. W. C. BORTON, Waukegan: I have had but little experience with the tuberculin tests. Dr. Watterson has had a good deal of experience with this test. He developed tuberculosis himself five years ago, went to Colorado, and after a year, all symptoms disappearing, he returned to Waukegan last spring to practice. He started a tent colony for the treatment of tuberculosis, has had a number of patients, and has obtained good results. He has used the Moro test in every case, and with one or two exceptions has obtained a positive result in every case in which the patient showed any symptoms of tuberculosis from the physical examination. In other patients who came to him in whom tuberculosis was suspected on account of anemia or run-down condition, but in whom there were no physical signs of tuberculosis, there were no results from the Moro test.

SYMPOSIUM ON NEPHRITIS

Significance of Albumin and Casts in the Urine

DR. ARTHUR R. ELLIOTT, Chicago: As a symptom, albuminuria is to be distinctly held in mind as not only an accompaniment of Bright's disease, but of acute and chronic inflammatory conditions of other portions of the genitourinary tract. It is frequently noted as a concomitant of disorders of digestion and elimination. In the zymotic diseases and acute infections it is very common. Certain static circulatory states, such as result from heart lesions, hepatic cirrhosis, and abdominal tumors produce albuminuria. Notwithstanding the diversity of its etiology, albuminuria, whether transient or permanent, must be regarded as pathologic. The so-called functional albuminurias (cyclic, orthostatic) constitute no exception to this rule. Although albuminuria may not necessarily mean serious organic mischief in the kidneys, it invariably points to some urinary or systemic perversion, and its presence, however slight, demands serious care and consideration before a decision is reached as to its being of no clinical significance. A form of albuminuria that is encountered during childhood and early adult life is so-called functional albuminuria. The characteristics of this form of albuminuria are that it is transitory, usually intermittent, and dependent on some special factor, such as muscular exercise, posture, cold bathing, or some particular article of diet, and, moreover, is not accompanied by the systemic and urinary indications of a true nephritis. There has been much

dispute regarding the nature and origin of tube casts. The oldest view is that they consist of coagulated fibrin derived from an exudate such as is found in inflammatory elsewhere in the body. This view is no longer tenable in consideration of the fact that casts unquestionably occur in the urine in conditions in which there is not the slightest sign of inflammation, such as renal congestion, and simple amyloid kidney. Moreover, casts do not give the same chemical reactions as fibrin. Their failure to occur in many cases of albuminuria and their appearance without albuminuria seem to indicate that they do not consist of coagulated albumin, as some have held. There is no fixed ratio between the amount of albumin in the urine and the number of casts. The occurrence of casts without albumin in those forms of infection and intoxication in which degeneration and disintegration of the tubular epithelium have been proved suggests that they are formed from these epithelial elements. Casts are always indicative of a pathologic process in the kidney, more particularly in the epithelial elements, ranging from a mere nutritional or functional disturbance to extensive destruction of the parenchyma. The freer from degenerative markings the cast cells are, the more acute it may be inferred is the degree of inflammation. A trace of albumin and hyaline casts in the urine are too often magnified in importance, and the clinical condition as a whole is often not sufficiently considered. Albuminuria and cylindruria have not the fixed diagnostic value they were once supposed to possess. In suspected renal disease the urine should be repeatedly examined and its fluctuations taken into account; no clinical construction should be placed on urinary findings until a careful investigation has been made of the symptoms and physical signs presented by the patient.

Value and Limitations of Salt-Free Diet and Restriction of Fluid in Nephritis

DR. CHARLES SPENCER WILLIAMSON, Chicago: The general consensus of opinion seems to be that chlorid retention does not occur to any considerable degree in the atrophic type of nephritis, as it does in parenchymatous forms. The French writers are still strongly impressed with the value of the milk diet. The régime lacté has become almost a fetish with them. The administration of water in nephritis is a more complicated subject, as more factors have to be considered. The necessity of obtaining a correct judgment in regard to the administration of water is imperative, because it is possible to bring about irreparable injury by a failure to recognize the indications for either its withdrawal or free administration. Following the work of Oertel and v. Noorden, the recent tendency has been to restrict the use of water on the ground that by reason of its absorption into the circulation, it increases the tension, thus adding to the work of the already overburdened heart. To summarize, it would seem that the restriction of the total fluids below 1,500 c.c., exclusive of the amount contained in food, may be quite as injurious as the excessive quantities formerly prescribed. In my opinion, when the extensive edema finally occurs in the contracted kidney, it is to all intents and purposes a cardiac edema and should be treated primarily as such.

Discussion on Nephritis

DR. JAMES B. HERRICK, Chicago: We should regard albumin and casts as always pathological, but not necessarily indicating disease of the kidney, or as indicating that the disease of the kidney, even though it be present, is serious. There is a tendency for us either to overestimate their importance, as was done several years ago, or to underestimate the importance of traces of albumin and the finding of a few casts in the urine. I fear we are inclined even now to overestimate the importance of these things and to condemn a man perhaps to Bright's disease when we find a trace of albumin or a few casts in his urine. With the electric centrifuge, casts are found in the urine of nearly every individual over the age of 40 or 45. A trace of albumin may be found under various circumstances, and is really not of much pathologic importance. The only way we can readily estimate such findings in the urine is to individualize, not to dogmatize, as Dr. Williamson has pointed out, or to estimate on the basis of any hard and fast rule. We must study, in other

words, the patient as a whole, and when we find albumin and casts in the urine, we should look on this as something that needs careful investigation. In one case we may find no other evidence of nephritis; we may find none of the cardiovascular changes, no anemia, no retinal changes, which can be looked on as due to uremic intoxication; while in another case, with no more albumin, no greater number of casts, we may put a serious interpretation on that case, in that we find deterioration of the blood, loss of weight, urinous odor to the breath, and definite cardiovascular changes.

DR. E. J. BROWN, Decatur: I have under observation what I consider a remarkable case of chronic parenchymatous nephritis. The patient came to me with albuminuric retinitis so advanced that the amblyopia was almost complete. The man could not read newspapers. He could barely walk around the house. I gave a bad prognosis. I put him on a milk, vegetable and fruit diet, and told him he could eat anything that came out of the ground. I was surprised at the ease with which he took this diet, which reduced his salt. There was a remarkable improvement in his eyesight, so that he can now read the morning papers. But I regard this improvement as only temporary. We are sometimes astonished at the length of time nephritics will live. I recall a patient with chronic parenchymatous nephritis whom I saw eight years ago, with profound anemia, and universal anasarca; the man is now well and running a store. He ascribes his cure to a six years' course of urotropin (hexamethylenamin). He said he took seven and a half grains a day for six years. I do not believe that the drug had much to do with the cure which was effected in his case; but he also took the treatment recommended for him, namely, a milk diet, and egg restriction. At any rate, the result has been remarkable in regard to the length of time the man has lived.

DR. H. J. STEWART, Chicago: In chronic interstitial nephritis more attention should be paid to the action of indican in the urine. We all know that indican is the result of intestinal putrefaction, and that probably the toxemia which results irritates the kidneys to such an extent that uremia, retinitis, etc., may be due to the presence of indican, or the intestinal putrefaction arises from toxemia in the intestinal tract.

DR. A. BELCHAM KEYES, Chicago: In our work on the peritoneum we have cases of peritonitis in which there is an enormous autointoxication from the peritoneal cavity, and we try by the use of opiates to bring about localization after operation and drainage. In these cases it is necessary for the kidneys to eliminate as freely as possible, and in many cases there are albumin and casts from the febrile condition and autointoxication disturbance. There is a dearth of knowledge as to what to feed such patients on to get results. For years I have used peptonized milk, which was not mentioned by any of the essayists. I would like to know what they think about it.

DR. ROBERT H. BABCOCK, Chicago: In chronic nephritis, anyone who has seen many cases must have observed that there are edemas that are hard and some that are soft; whereas in all cases of cardiac disease in which there is edema one should estimate the volume of chlorids in the urine. Nevertheless, in a purely empirical and rough fashion it will give considerable information as to the value of restricting or entirely eliminating salt from the diet. If the edema is soft, restriction or total abolition of salt from the diet will usually prove most efficient in its reduction. In the hard edemas dechloridization of the diet is of small value, in my experience. In many cases of chronic nephritis, without much edema, we see patients who suffer a good deal from a sort of paroxysmal dyspnea. In some of these the heart does not seem so much at fault, and it is rather difficult to determine just why we look on it as toxic, and perhaps in some cases it is purely toxic, but it has been my experience that the restriction of salt in the diet is many times most happy in its effect in the relief of some of these cases of dyspnea. In a case of chronic nephritis in which there is no edema, I believe it is a good plan to impress on such patients the importance of cutting down their salt, else the time will come when they will develop edema. (To be continued)

Telephone Company Not Liable for Death Due to Inability to Use Line to Call Physician

The Court of Civil Appeals of Texas says, in *Southwestern Telegraph & Telephone Co. vs. Solomon*, that the evidence showed that at about 2 a. m. Mrs. Solomon was taken violently sick in childbirth, and that her husband tried to call the family physician over the company's telephone in which he had a rental interest, but could not get connection with the central office because the telephone was out of order, due to the negligent condition of the ground wire. He then got on his horse and went to the house of the family physician, the one he had been trying to get over the telephone, and found him sick and unable to go. He then tried to get the central office from this physician's house to get another physician, but could not get central from there. He then went to the central office, found it locked and tried to get in, but could not. He then went to a nearby telephone, called central, and summoned another physician, who went to the house, but got there too late to save Mrs. Solomon's life. She had given birth to a child and died from hemorrhage of the womb, which might have been stopped if a physician had arrived sooner.

Was the telephone company liable for damages? The court holds that it was not. It thinks the damages in the circumstances were too remote and were not such as both parties would reasonably have understood and contemplated as likely to result from the breach of the contract or the negligence of the company.

If there had been a specific contract with the telephone company by which it had agreed to transmit or to furnish facilities for transmitting this particular message to the physician, or if the object and purpose in having the physician summoned over the telephone to immediately attend the woman was previously made known in proper time to the company under the general contract of telephone service, then there might have been some analogy between this case and the various telegraph cases where telegraph companies have been held responsible for such damages for failure to promptly transmit and deliver the message. But here the unusual situation and condition of the woman was not known to the company, and it had no notice or previous notice of the importance or urgency of a communication to a physician and his summons to come at the time to attend her.

Nor could the suspense and anxiety suffered by the woman because of the fact that a physician failed to reach her sooner than he did be fairly and reasonably considered in the circumstances as arising naturally and in the usual course of things from the failure of general telephone service in the absence of notice to the company of the object and purpose of the deceased in having the physician summoned to come and attend her.

Changing View of Power to Order Physical Examinations in Federal Courts

The United States Circuit Court of Appeals, Eighth Circuit, says, on the appeal of *Chicago & Northwestern Railway Co. vs. Kendall*, a personal injury case brought by the latter party, that on the trial the plaintiff took the witness stand in his own behalf, and while undergoing cross-examination was asked to expose his knee to the jury for inspection. After some colloquy his counsel directed him to comply with the request. A question was then raised as to whether the injured knee was different from the other knee, and a jurymen suggested that the matter could be better determined by an examination of the other knee, and, thereupon, the plaintiff exposed that knee also. Counsel for the railway company then stated that he had in the courthouse two reputable physicians, and asked the plaintiff if, with his knees exposed, he would permit these two physicians, in the presence of the jury, to examine him. This the plaintiff refused to do.

A motion was then made that the plaintiff be required to submit his knee to the examination of physicians selected by the defendant company, either in open court, or at some other

place, before the conclusion of the trial. This was overruled on the ground that a United States court has no power to require a party to submit to a physical examination, except in those states where the local statute authorizes it, and there is no such statute in Iowa, where the trial took place.

But the United States Court of Appeals holds that it was error to refuse to compel the plaintiff to submit his knee to surgical examination under the circumstances. It says that in this case it was not dealing with an application for a surgical examination in advance of the trial. Here the plaintiff at the trial voluntarily exhibited his knee in open court for inspection. Having done this, it was beyond his power to arrest the investigation. The defendant and the court were entitled to employ any agency in its examination which would aid in the determination of the issue on trial. It is universally held that where an inanimate object is produced on the trial of a case it is subject to any legitimate examination and test which will elucidate the matter in dispute. It may be submitted, for example, to chemical treatment, or to examination by the microscope. Simply looking at the plaintiff's knee with the eye of a layman furnished little aid in determining its condition. He himself maintained that there were no external evidences of injury. Whether there were hidden ailments could only be discerned by the skill of a surgeon, and the defendant and the court were as much entitled to turn the eye of a surgeon on the plaintiff's knee as they would have been to look at a blood stain through a glass. Having exhibited his knee to the jury, it became a part of the evidence, and the mere accident that the thing exhibited was part of a human body could only qualify, and not defeat, the right of complete investigation.

With regard to *Union Pacific Railroad Co. vs. Botsford*, 141 U. S. 250, in which the Supreme Court of the United States decided that federal courts do not possess power, independent of statute, to compel a plaintiff in an action for personal injuries to submit his body to the examination of physicians, it is pointed out that there the application was made in advance of the trial, and that the Supreme Court has already limited the *Botsford* decision in *Camden Railway Co. vs. Stetson*, 177 U. S. 172. Also, that the decision is at variance with a large majority of the state courts. The rule which it declares has been abrogated by statute in many jurisdictions where it once prevailed. This is the case in New York, New Jersey, Great Britain, Canada and Australia. Therefore this court does not feel disposed to extend the decision beyond the facts there involved.

When Insanity or Delusion No Defense to Crime

The Supreme Court of Kansas says, in the homicide case of *State vs. Arnold*, that it is the condition of the mind of the accused which determines whether he is criminally accountable for an act denounced by the statute as criminal, and not the name of the mental infirmity, if such infirmity exists. The law recognizes every form of insanity or delusion which renders an accused mentally incapable of knowing the nature and quality of an act he is doing, and that what he is doing is wrong, as relieving him of criminal responsibility for the act; but no delusion or mental weakness which falls short of rendering the mind incapable of such discernment obviates the criminal character and penalty of the act. That is to say, no delusion or impulse excuses one from the penalty for an act committed which the statute denounces as criminal, unless such delusion or impulse unseats the reason and judgment so far that it can be said beyond a reasonable doubt that the accused at the time of the act did not know the nature and quality thereof and did not know that what he was doing was wrong.

Implied Power of President of Corporation to Employ Physician

The St. Louis Court of Appeals affirms a judgment for the plaintiff in the case of *Weinsberg vs. St. Louis Cordage Co.*, which was brought by a physician and surgeon to recover compensation for surgical services rendered in performing an operation on one of the defendant company's employes, at the instance and request of its president. The court says that it was conceded that the defendant was a manufacturing com-

pany, incorporated under the laws of Missouri, and, in view of that fact the court entertains no doubt whatever as to its being within its power to employ a surgeon to attend an employé seriously injured in its factory.

In volume 5 of his Commentaries on the Law of Corporations, section 5840, Judge Thompson says: "An implied power will be ascribed to any corporation employing labor to incur expenses on account of injuries received by its employés in the line of their employment, in the absence of any express statutory grant of such power. This implication rests on the most obvious grounds of justice and humanity." There certainly ought not to be any question of doubt, with respect to the authority of the chief executive officer of an incorporated company, of the character here involved, to execute the power. When a catastrophe occurs in its factory, the corporation ought not to be expected to assemble its board of directors in order to exercise the implied power referred to. There is certainly an emergency power, incident to the office of president of such an institution.

It is no doubt true that where a physician or surgeon renders services to one at the mere request of a third person, on whom there rests no obligation to provide such service, the law will not imply a contract to pay on such mere request. On this question the law is succinctly and accurately stated as follows: "When a person requests a physician to perform services for a patient, the law does not raise an implied promise to pay the reasonable value of the services so rendered, unless the relation of the person making the request to the patient is such as raises the legal obligation on his part to call in a physician and pay for his services."

In view of the law thus stated it was contended that no recovery should be allowed in this case, for the reason that the trial court found there was no express promise to pay. That to say, it was argued that the case was one in which the defendant declined to imply a contract, and therefore to sustain a recovery an express contract must be shown. Had the trial judge found a mere request on the part of the defendant company, and nothing more, the argument would have been persuasive indeed. However, this court does not understand that because there was no express promise it followed that there might not be an actual contract, as distinguished from one implied by law. Although the law will not imply a contract, if there be an actual one, it need not be express.

It appeared that the trial court found, not only that the president requested the services, but that he intended the defendant company should pay therefor. It also conclusively appeared that the plaintiff intended to charge. In these circumstances the fact of a contract between the parties was established by the testimony. Although not express in all of its details, it nevertheless constituted a contract. There were present competent parties, the subject matter, a sufficient consideration, and, above all, the meeting of minds; for it appeared that the physician intended to charge, and the company intended to pay. Under these circumstances it was unnecessary to refer to the law for implication, for the contract was established as a matter of fact.

In the absence of express terms as to the amount of compensation, the law would imply a reasonable one. Whether the injured employé received his hurt through the negligence of the employer or not was immaterial. A physician, called by the employer in an emergency to treat a man severely injured, ought not to be required to inquire first as to whether the man was injured through the negligence of the employer, by accident, or as a result of his own carelessness. And then, too, if such were to be treated with as an element of the defendant's liability in a case of this character, it would introduce the collateral issues of negligence, into every case in which a physician seeks to recover on a contract with the employer for compensation in treating an injured employé at its request.

Admissible Evidence in Abortion Case

The Supreme Court of New Jersey holds, in the case of *State vs. Fletcher*, that on the trial of an indictment for abortion, evidence of the physical condition of the woman at a time some ten days subsequent to the time when it is alleged the operation was performed is admissible. More

particularly, the testimony in question in this case related to an operation performed by surgeons on the woman some ten days after the abortion, the testimony being as to what this operation revealed as to the woman's physical condition. Such testimony was clearly admissible.

Mortuary Tables Not Applicable to Asthmatics

The Supreme Court of Mississippi holds, in *Mississippi Cotton Oil Co. vs. Smith*, that it was error to admit mortuary tables in evidence when the testimony clearly showed the decedent to be an asthmatic and a witness expressly testified that, being an asthmatic, he was not in the class embraced by the mortuary tables. It was expressly held in the case of *Railroad vs. White*, 82 Miss., 471, the court says, that these mortuary tables only show the probable age which a sound and healthy person belonging to the class may expect to reach whose age is given, and that it would be error to permit the introduction of mortuary tables to show the life expectancy of one not within the class of persons for whom such tables are prepared. The same doctrine is laid down in *Telephone Company vs. Anderson*, 89 Miss., 745, and *Railroad vs. Crudup*, 63 Miss., 303, and is well settled.

Transfers from Prisons to Insane Asylums

The Supreme Court of New Jersey says, in *re Herron*, that where a person under sentence of imprisonment as a punishment is transferred from a penitentiary to an asylum, it is not a transition from imprisonment to liberty. Whether in a hospital or a prison, the convict is a prisoner. Indeed a prison may have a ward for insane patients, and an asylum a ward for insane convicts. It is true that in the asylum he may escape hard labor, but so may any sick convict in the state prison. The removal of a prisoner, who is to serve out his sentence of imprisonment, to a place provided with all the appliances for medical treatment, is a humane provision, having a practical purpose. As remarked by Justice Parker: "The prisoner has his life to live, and public policy requires that he be so treated as to live it to the best advantage." That the prisoner remain in confinement in an asylum until fully restored to reason is a humane substitute for confinement in a prison where there are no adequate means for mental treatment. When, however, a person is confined to await the execution of a death sentence, the conditions are radically different. The removal to an asylum for treatment in such a case would be merely a removal for the purpose of restoring him to that degree of sanity which, at common law, was not inconsistent with his execution.

1. *Study of Anthropology*.—Woodruff says that while biologists for half a century have been talking about adaptation to environment, the medical profession has entirely ignored it, commonly regarding the differences between types of men as of no significance; consequently no investigations have been made. A great obstacle to the determination of characters due to the selection of variations, is the fact that a modification may appear generation after generation so long as the cause acts, though such acquirements are never hered-

italy. Another disturbing factor is the effect of use or disuse. This, too, is non-hereditary in character. It behooves us, then, to take up each character and determine why it exists. Speaking generally, there is something about tallness and bulk which makes it an advantage in cold places and a decided disadvantage in hot ones. We lack adequate data to form a scientific theory concerning this, but the hypothetical explanation is that surface varies as the square, and weight as the cube, of length, so that heavy men have less radiating surface than thin men of equal height. This is a decided advantage in retaining body heat in cold climates, but prevents sufficient radiation and breaks down the nervous system in the tropics. This is a practical matter. Among thousands of cases investigated, not one overweight attained 80 years, while 44 underweights passed it. What is the cause? This is a typical instance where preventive medicine is waiting for an acceptable theory from anthropology and anthropometry is waiting for pathologic facts on which to form a judgment. The nasal index—or the width of the nose divided by the length—which is greater in tropical natives than among inhabitants of cold climates, and its relation to respiratory diseases, also demand an investigation. Woodruff's own investigations have been entirely confined to the use of the pigments of the skin, hair and eyes. We are dependent for health on small amounts of light, but light in large amounts is lethal, and even in small doses may be unduly stimulating, so that the limit of safety is far below the point generally accepted by the medical profession. Nature is always removing the specimens insufficiently protected, so that in any place people in time become pigmented in proportion to the maximum intensity of light. The evidence is fairly conclusive that blonde races tend to disappear when they migrate to lands of excessive sunshine. These phenomena are occurring in America, and attention has repeatedly been called by anthropologists to the increasing brunette character of our population. While it is true that there are more blondes in the United States than ever before, that is due to the new arrivals. In New England the blondes do not maintain their proportion, because of a higher death rate or a lower birth rate, or both. What diseases are carrying them off in the rest of the country? Here the medical profession can be of immense value to anthropology by simply recording the complexion of patients of each group of diseases, whereby a study can be made of those most affecting brunettes and blondes, respectively, and preventive and therapeutic measures be developed. The United States affords a great field for investigation in these problems, for it offers many types of people, many varieties of diseases, and all kinds of climates, in each of which there are specimens from every region of the globe. Woodruff calls the idea that we are producing a new type by mixture, a "prevalent delusion." Nature has been mixing Europeans for thousands of years, and has been unable yet to produce a type fit to live everywhere, from Scotland to Sicily, and she will be equally unsuccessful here. Amalgamation is a biologic absurdity. No American type has yet been produced, and Woodruff finds, by a daily experience of twenty two years with soldiers, all of whom are dressed alike, that until questioned it is impossible to distinguish recently arrived foreigners from natives of many generations' residence. The same types are found in each class.

4 **Blood Pressure on Life Insurance.**—Faught says that recent increase in clinical data, which is the result of finer methods of observation, demands greater recognition by the practicing physician and the medical examiner. To facilitate a better understanding of the conditions encountered, more care should be exercised in the employment of clinical terms. More careful study should be made of the vessels in an effort to distinguish atheroma, hypertension, and arteriosclerosis. The sphygmomanometer is a valuable aid in determining arterial tension, and in differentiating diseases of the cardiovascular system. Our present knowledge of the subject of diseases of the circulatory apparatus demands a critical revision of the present examination questions to be answered by the life insurance examiner. He describes a sphygmomanometer of his own devising.

Medical Record, New York

May 22

- 8 *Neurogenic and Myogenic Theories and the Modern Classification of Cardiac Arrhythmias. S. J. Meltzer, New York
- 9 Infant Mortality. W. L. Stowell, New York
- 10 *Instantaneous Radiography in Less than One Hundredth Second—A New Method of Radiography. F. Dessauer, Aschaffenburg, Germany
- 11 Economy in Major Anesthesia: More Particularly as to Ethyl Chlorid. R. H. M. Dawbarn, New York
- 12 *Smoked Torics—A Menace to Health. P. R. Wood, Marshalltown, Iowa.

8. **Neurogenic and Myogenic Theories.**—Meltzer presents a careful review of the evidence in the question between the neurogenic and myogenic theories of cardiac action from the viewpoint, "not of a warrior taking sides with one of the camps," but simply from that of "a war correspondent telling the news from the battlefield." He reports that the myogenists have won the day, the majority of physiologic and medical investigators being converted to their views. The theory amply justifies its existence by its productivity. Fruitfulness is the only criterion and the only requirement of an efficient theory. The myogenic theory recently exerted a wholesome influence on medical investigation, and will continue to reign so long as it is productive. Meltzer then discusses the pathologic aspects of the problem, namely the arrhythmias. He briefly outlines the indispensable facts in physiology for the understanding of their modern interpretation. He discusses briefly, the methods employed in studying human arrhythmias; and finally, the classification and interpretation of the arrhythmias as they are advocated at present by leaders in this new field of clinical research.

10. **Instantaneous Radiography.**—Dessauer reviews the advances made in the question of shortening exposure, by Rosenthal, Rieder and Eymann. Dessauer has made a series of pictures of the extremities of the thorax, the left superior part of the lung and the heart, in less than one-hundredth of a second. These were only slightly, some even not at all, under exposed. The advantage of this method is that it is no longer necessary to fix the patient carefully. The entire manipulations in radiographing do not require more trouble than the pulling of the trigger of a gun.

12. **Smoked Torics.**—Wood scores the smoked toric coquille much used and even prescribed by the profession as a shade for weakened sore eyes. It has an unmeasured and irregular refraction index ranging from 1/12 to 1/2 diopter minus. This is enough to cause pathologic local conditions and reflex functional neuroses in neurasthenics as is shown by the way that such conditions disappear on correction of such a defect. He describes a case in point. Glasses of the proper kind are plain and possessed of no refracting power.

- 13 *Functional Relation of the Tonsil to the Teeth. G. H. Wright, Boston
- 14 Short Description of Wertheim's Radical Abdominal Operation for Cancer of the Cervix Uteri, with Report of Eight Cases. H. T. Hutchins, Boston
- 15 *Value of Ethyl Chlorid as a General Anesthetic. A. H. Miller, Providence, R. I.

13. **The Tonsils and the Teeth.**—Wright describes 19 cases and discusses the lymphatic anatomy of the region to show the connection between the teeth and the tonsils, and in conclusion offers the following observations:

- 1 When a tonsil is normal, infection from the external surface is rare
- 2 Secondary infection through the lymph channels is the usual source
- 3 There are four periods of molar eruptions, with some variations in time when the tonsils may enlarge without infection or inflammation viz., at two years, six years, twelve years and seventeen years
- 4 Tonsils though slightly enlarged when not infected return to normal with complete eruption of the teeth
- 5 Diseased teeth are a prolific source of enlargement of the glands through proximity of membranes, either directly, by infection, or by toxins
- 6 In the treatment of the tonsil by the specialist, may we not include as a routine the observation as to carious teeth and a recognition of these four periods of eruption coincident with slight enlargement?

15 **Ethyl Chlorid as a General Anesthetic.**—Miller has administered ethyl chlorid by the handkerchief method 6,643

times. He briefly discusses the history of ethyl chlorid, its advantage as a general anesthetic, and the records of supposed fatalities due to ethyl chlorid, and shows the proportion of deaths to be 1 to 8,759 cases. In conclusion he says that the relative danger from an anesthetic depends on two factors: (1) The margin of safety of the drug; (2) the character of the danger signs. The margin of safety of an anesthetic may be represented by the proportion of the drug which may be administered beyond the amount required to produce anesthesia without causing symptoms of danger. Nitrous oxid has a small margin of safety, but the danger signs are so marked that nitrous oxid anesthesia is the safest known. Ether has a fairly large margin of safety and well-marked danger signs, so it is a safe anesthetic. Chloroform has but a small margin of safety and the danger signs are readily overlooked. It is always a dangerous anesthetic, but especially so in inexperienced hands. Ethyl chlorid has a large margin of safety, but the danger signs are not marked. While it is very safe when administered by an expert, it may be very dangerous in unskilled hands. With an expert administrator, it should be safer than ether but less safe than nitrous oxid. With an unskilled or careless administrator it is probably more dangerous than ether, but not so dangerous as chloroform.

25. **Heller's Test.**—Rodriguez says that in bilious remittent fevers with albuminuria, the liver not being deeply affected, there is to be noticed, underneath the milky ring, a wide, deep red band, which, together with microscopic examination of the blood, settles the diagnosis. When albumin is absent the red ring is replaced by another, almost black, but with a red shade on refraction, which he considers characteristic. When the liver tissue is affected the ring is reddish black. In yellow fever he presents the following as a new sign: The white milky ring of Heller's test due to albumin, which is early visible in yellow fever, is to be observed on top of a greenish band, which is of fatal omen if it becomes deep green. He reports a doubtful case in which diagnosis was made by means of this sign and subsequently verified.

26. **Tic Douloureux.**—Tucker reports 13 cases, from which he draws the following conclusions:

- 1 Malaria and rheumatism were prominent factors in causing the tic in these cases.
- 2 Sodium salicylate in the rheumatic cases, and quinin in the malarial ones, pushed to limit of tolerance is of marked benefit.
- 3 The effect of treatment is enhanced by a week's rest in bed, purgation, and a nourishing, but not too rich diet.
- 4 As a rule medical means should be first tried then alcoholic injection. If these are not effective the peripheral operation should first be performed, and the Gasserian ganglion operation only as a last resort.

39. **Fat in the Islands of Langerhans.**—Symmers reports a study of the fat content of the islands of Langerhans from a purely morphologic view, in a series of 73 unselected autopsies, with Sudan 3 as a stain. His observations, he believes justify the following conclusions:

1 The presence of fat in appreciable amounts in the islands of Langerhans, contrary to certain observations recorded by Stangl, is invariably pathologic.

2 Fat accumulates in these situations in individuals at or beyond middle life in response apparently to certain changes brought about in the cells by the prolonged use of alcohol. Thus, out of 32 alcoholic subjects excessive accumulations of fat were present in the islands of Langerhans in 24 instances (75 per cent), while in 41 non-alcoholic subjects varying in age from a seven months' fetus to 68 years the islands were wholly free from fat or occasionally fat was to be made out in isolated islands in entirely negligible quantities.

3 The islands of Langerhans may be completely devoid of fat in genuine diabetes mellitus.

4 There would also seem to be sufficient data to warrant the suggestion that the occurrence of fat in excessive quantities in the islands of Langerhans is a factor in the production both of the intolerance for sugar manifested by alcoholic subjects and of the alimentary glycosuria so frequently to be observed in individuals of this type.

40. **Hemolysis and Agglutination Tests.**—Epstein and Ottenberg point out that the quantity of blood necessary for controlled tests in all serum reactions exercises a great limitation. They record a means for performing a large number of tests with a very small amount of blood. Two methods of obtaining the blood are described, one with a small syringe (10 to 15 c.c. capacity) from a vein at the end of the elbow and the other by deeply pricking the lobe of the ear. One or two c.c. of the blood are then put in a tube containing an excess of salt citrate solution, centrifuged, washed, and made up to the desired percentage in normal saline solution. When sufficient blood has been drawn by the syringe, the remainder is placed in small slanted test tubes and the serum allowed to separate by clotting. Small glass capillary capsules are used to obtain the serum, and when three quarters full, the capillary end is sealed, the blood allowed to clot, and the capsule centrifuged. When it is nicked with a file it is broken open and the serum can be pipetted off. For making the mixtures, small pipettes (from four to five millimeters' caliber), fitted with rubber nipples, are used. The tips of these pipettes, drawn to a length of two or three inches, are marked at an arbitrary point with a blue pencil. The suspension of erythrocytes is drawn up to the mark. By drawing this a little farther into the pipette one allows a small bubble of air to enter the tip, and then, in a similar manner one or more volumes of the serum are drawn into the same pipette. Thus definite proportions of the ingredients can be accurately measured. By running the cell suspension and serum gently up and down in the pipette they become thoroughly mixed. The entire mixture is then drawn up into the body of the pipette and the tip is sealed in a flame. The pipettes may be kept upright by sticking them into a tumbler

of sand. These narrow tubes serve in every detail the purposes of the larger test tubes generally used.

43. **The Moro and von Pirquet Reactions.**—Patterson reports the results of a comparative investigation in 171 cases, and concludes that the Moro reaction is absolutely harmless and simple; better adapted to adults than the von Pirquet test, and while it produces a reaction about as frequently as the ocular reaction in the tuberculous and in the clinically free cases it is devoid of danger.

44. **Idem.**—Hamman and Wolman report in detail a lengthy investigation into the cutaneous and conjunctival reactions and the relations between these and the subcutaneous test. Their experiments are tabulated and their conclusions are summarized as follows:

- 1 In adults the cutaneous tuberculin test is of value in diagnosis only when it is negative
- 2 The frequency of its occurrence runs roughly parallel with that of the subcutaneous test
- 3 The conjunctival test is of value principally on the positive side, a definite reaction indicating the presence of an active tuberculous lesion
- 4 The most satisfactory results are obtained by using the two tests simultaneously. Both being negative speaks for the absence of any active tuberculous focus, both being positive, for its presence, the conjunctival negative and the cutaneous positive give no information of value
- 5 We can not admit that the conjunctival or cutaneous reactions have any prognostic value
- 6 The same conjunctiva should never receive a second instillation. The reaction so obtained is valueless for diagnosis and the procedure not without danger
- 7 We believe that with proper precaution the conjunctival test may be used without danger of permanent injury to the eye
- 8 We have been unable to confirm in any particular the claims Dietrich makes for his differential cutaneous reaction.

45. Abstracted in THE JOURNAL, May 29, p 1785.

47. **Edema of the Lungs.**—Emerson urges artificial respiration, which he believes would prove more prompt and effective than any medication whenever the edema and cardiac incompetence are of sudden development and due to causes likely to prove of brief duration or removable by appropriate treatment; and it would at least give mechanical relief to the overloaded heart muscle while arterial relaxation and cardiac stimulation are being effected by drugs. Edema due to cardiac failure in pneumonia, or the inevitable terminal feature of chronic endocarditis, naturally can not be expected to respond to such temporary relief measures.

49 **Opsonins.**—Hektoen discusses the final results of research in its general bearing on the work on opsonins. He outlines the theory and discusses the resistance offered by microbes under different conditions to antibodies, and more particularly to opsonins, as exemplified in the bacillus carrier. Recent experiments have resulted in complete harmony with the early teaching of Metchnikoff, that as a microbe grows in virulence, its resistance to phagocytosis increases. The passage of pneumococci, streptococci, and other bacteria, through suitable animals has been at the same time more virulent and more resistant. Cultivation outside the body causes reversion to less virulent states. Investigating this property of pneumococci to develop such strong defense against phagocytosis, Rosenow found that extraction of autolysis of virulent pneumococci brings into solution a substance or group of substances that neutralize the pneumococcal opsonin in human serum, but not other opsonins. After extraction of this substance, which is thermostabile and insoluble in alcohol or ether, virulent pneumococci unite with opsonin and become phagocytizable, while avirulent pneumococci, on treatment with extracts of virulent strains, not only become resistant to phagocytosis in the test tube, but also, to some degree, virulent for animals. It may be said, then,

that the properties called virulence in pneumococci appear to depend, to a very large extent if not wholly, on the formation of an actual substance—"virulin"—which may be extracted and studied by itself. It is hoped that this demonstration may prove a basis of departure for new and fruitful work in pneumococcus and similar infections.

56. **Dilute Renal Excretions.**—Macallum and Benson undertook to solve the question as to the filtration or secretion theory of the formation of urine by analyzing the dilute urine produced by drinking large quantities of water. They reason that if the production of urine is due simply to filtration, such urine having passed through the tubules too rapidly to be modified by reabsorption should contain the inorganic salts in the same proportion as does the blood plasma. They found, however, that the relative value of potassium and chlorine is never that which obtains in the blood plasma, and is usually much greater than that which is obtained in the concentrated urine, formed immediately before the experiment began. This increase in the value of potassium as related to chlorine is due to a "lag" in the diminution of the secretion of the potassium, as compared with that of the chlorine during the decrease in the concentration. This lagging behind, or "hysteresis" may be found again, though not always, when the urine begins to increase in concentration,

K

the value of — then falling because the potassium slowly,

Cl

and the chlorine (especially of sodium chloride) rapidly, increases. In some cases, notably toward the end of a series, the rate of the excretion of the potassium, relatively to the chlorine, may rapidly increase or rapidly decrease. The elimination of water is due not to filtration, but to the physiologic activity of the renal membranes involved in the elimination. The removal of potassium salts and of chlorides from the blood by the kidneys is due not to filtration, but to forces which may be termed "secretory," that is, it is caused by an activity which is apparently selective, or differential, but which may be explained as due to difference in solubility of the different inorganic constituents of the plasma in the secreting membrane. The solubility, either relatively or absolutely, or both relatively and absolutely, would be altered by changes in the constitution of the membrane brought about by the action on it of unusual constituents of the plasma or of constituents of unusual proportions.

59 **Human Pancreatic Juice.**—Bradley had the opportunity to examine human pancreatic juice, derived from a traumatic fistula which probably communicated with the accessory duct of the pancreas. He summarizes a part of his results as follows:

- 1 The specific gravity averages about 1010
- 2 Alkalinity is due to normal and bicarbonates, chiefly the latter. The secretion varies from a $\frac{N}{20}$ to a $\frac{N}{10}$ bicarbonate solution.
- 3 No definite relation could be established between diet and enzyme content. The enzymes are found to vary considerably, with the exception of amylolysin, which appears to be more constant in amount from day to day. A slowly secreted juice is more concentrated in its solid content, its carbonates, and lipase
- 4 Rennin, invertase and lactase were not found
- 5 Manganous sulphate was not found to accelerate starch digestion, nor was bile
- 6 Pepsin was found in about half of the samples collected. Inactive samples could be readily activated with enterokinase prepared from the intestines of dogs and cats. Inactive samples be

came gradually active on standing, though saturated with toluol and in some cases chloroform.

7. The lipolysis of olive oil and ethyl butyrate varies in parallel directions in the different samples. The author believes that a single enzyme accomplishes both digestions.

Journal of Cutaneous Diseases, New York

May

- 63 *Chronic Itching Papular Eruption of the Axillæ and Pubes: Its Relation to Neurodermatitis. J. A. Fordyce, New York.
64 Therapeutic Testing of Dermatologic Remedies. H. Fox, New York.

63. Itching Papular Eruption of the Axillæ and Pubes.—In a well-illustrated article, Fordyce reports a case and refers to two others of a condition of thickened skin, attended by an excessive amount of itching, and made up of papules or diffuse patches, not corresponding to typical lichen planus lesions, which, by many, are considered as secondary eczema on the one hand or as related to the lichen group on the other. He urges that more attention be given to Brocq's conception of this group under the term lichenification. He includes his case under the class of eruptions described by Brocq under the name *névrodermite chronique circonscrite*. The symptoms are a limited pruritus with subsequent pigmentation and exaggeration of the natural lines, the skin becoming by degrees thickened, and distinct lesions more prominent as a result of scratching. The regions most often attacked are the neck, upper and internal surfaces of the thighs, the loins, intergluteal folds, inferior and external part of the leg, the scrotum, labium majus, the waist line in women, the popliteal and axillary folds, and the palms and soles. He discusses the histology and states that the similarities between his case and those of Brocq are more marked than the differences. Pending a more positive knowledge he feels justified in calling this distressing affection a variety of neurodermatitis, probably of toxic origin.

67 *Renal Complications of Acute Gonorrhea. Dr. Stoyantchoff, Veliko-Tirnovo, Bulgaria.
68 *Simple Method of Estimating Ammonia in the Urine, Suitable for Clinical Purposes. G. C. Mathison.

67. Renal Complications of Gonorrhea.—Stoyantchoff says that the frequency of albuminuria in the acute stages of gonorrhea demands more attention than it has hitherto received. In most cases the nephritis is metastatic, though in some it is due to extension. He discusses these types and states his belief that the charge that they are due to the use of balsams is greatly exaggerated. The prognosis in albuminuria arising during gonorrhea is usually favorable, though some cases of ascending infection and of general infection with edema and anasarca are of serious prognosis. The treatment of renal complications during gonorrhea is that of acute nephritis, with an absolute milk diet as its basis. In the ascending type the cystitis should be treated at the same time.

68. Estimation of Ammonia in the Urine.—Mathison describes Malfatti's simple and rapid method of estimating the ammonia in the urine. It depends on chemical reaction that takes place when a solution of an ammonium salt is treated with formaldehyd. He has found that the accuracy of the method can be increased by adding 15 grams of powdered, neutral potassium oxalate to the urine and shaking before titrating. In all the urines examined the formaldehyd method gave higher results—about 15 per cent.—than the Folin method.

72 *Sea-Water Treatment Given by Subcutaneous Injection, with Results Obtained in Children. T. Le Boutillier, Philadelphia.

69, 70. Abstracted in THE JOURNAL, July 11, 1908, p. 156.

71. Pepsin in the Infant's Stomach.—Ramsey reports a

series of observations and laboratory investigations, from which he draws the following conclusions:

1. The gastric juice of normal breast infants contains pepsin.
2. The stomachs of infants suffering from acute digestive disturbances usually contain pepsin.
3. The stomachs of infants suffering from pylorospasm contain both pepsin and hydrochloric acid in greater quantity than the stomachs of normal infants of the same age.
4. The stomachs of chronic atrophic infants frequently contain no pepsin.
5. When these chronic atrophic infants begin to improve in health and to gain in weight, the stomachs again contain pepsin.
6. The gastric juice of normal infants is capable of transforming proteid into peptone, and it is able to do this without the addition of any other acid than that found normally in the stomach.
7. The pepsin in the gastric juice is capable of active digestion when lactic acid and no hydrochloric acid is present.
8. Both hydrochloric and lactic acid may be present in the gastric juice without pepsin, and pepsin may be present without either hydrochloric or lactic acid.

72. Abstracted in THE JOURNAL, April 17, 1909, p. 1276.

73. This article was published in THE JOURNAL, May 1, 1909, p. 1390.

74. Gangrene of the Vulva Following Abortion.—Markoe reports a case, with colored illustration, of moist gangrene of the vulva, vagina, and cervix, which was operated on, all the gangrenous tissue being cut away and care taken not to invade the underlying normal tissue. The conditions came on about ten days after an abortion at six months. The value of fresh air in the treatment of this case is emphasized and a plea is made for the extension of the method in all septic cases. The pathology of the condition is discussed.

75. Eclampsia and Toxemia of Pregnancy.—Welch contrasts the opposing views in relation to the various forms of toxemia of pregnancy, one school recognizing two clinically distinct entities, the other considering the different forms of toxemia of pregnancy, including eclampsia, as closely related, if not identical, conditions. He presents the findings in 12 cases in which the clinical diagnosis was made of either eclampsia or toxemia of pregnancy. He discusses the various etiologic suggestions that have been made.

88 Ligation of Common Iliac Artery Under Unfavorable Conditions. E. Lanphear, St. Louis.
89 Penetrating Wound of Abdomen without Symptoms. C. H. Jaeger, New York.

82. The Visceral Crises in Skin Diseases.—Silver discusses the importance to the surgeon of the visceral crises in the erythema group of skin diseases. He quotes Osler's classification, into 5 groups, of which 3 are of importance to the surgeon, as being likely to lead to operation on a mistaken diagnosis. He has found 9 cases, on examination of the literature, in which the patients were operated on, and adds a case of his own in which the patient was recently operated on, with

2 cases examined after death. He reports his own case in full. The groups of importance to the surgeon are (1) those cases in which the colic occurs in connection with pure angioneurotic edema (Quincke's disease); (2) those in which there is arthritis, associated with erythema or purpura and colic—the group described by Henoch; (3) a group most difficult to recognize, in which there is only recurring colic and nothing else. Silver discusses angioneurotic edema and Henoch's purpura, with the differential diagnosis between the latter and intussusception and appendicitis respectively. His experience with one case and studies of reported cases, lead him to emphasize Osler's practical lesson, namely, "first, in children with colic the greatest care should be taken to get a full history, which may bring out the fact of previous attacks, either of skin lesions or of arthritis, or of intestinal crises; and secondly, make the most careful inspection of the skin for angioneurotic edema, purpura or erythema." and Silver adds, in an accurate examination of the blood, with a differential count, we have the most important aid in differentiating those cases which need surgical treatment.

83. **Fluorescent Salts in Surgery.**—Pleth and Pleth report results of the application of a 5 to 10 per cent. watery solution of eosin, covered with a thin layer of cotton to exclude dust and exposed to sunlight in stitch abscess, suppurating incised wounds after operations for osteomyelitis, in infected joints and eczema; also by injection in gonorrhea, and in combination with copper sulphate internally in actinomycosis. They report also the usefulness of scarlet red suspended in olive oil, vaselin or zinc ointment in proportion of from 5 to 10 per cent. The wound should be thoroughly dried, and the salve applied, not too thickly, and allowed to remain for from 12 to 24 hours, when it should be removed, and the wound covered with plain vaselin or olive oil. This treatment is renewed every 2 or 3 days. Enormous skin defects have been remedied by this method. In spite of the filthiness of the Mexican Indians and of their insanitary surroundings the good results uniformly obtained speak for the value of the treatment. The non-toxicity of eosin and scarlet red permits of their use in almost any place. The only drawback is that they stain the clothes.

85. **Scar Tissue.**—Duncan describes the technical details in operating which tend, by reducing irritation and producing accurate approximation, to bring about scar-free healing. The incision should be made with the scalpel at an angle of 60 degrees with the perpendicular. The advantages are cosmetic, lessened cause for pain and deformity, and less liability to keloid. He particularly states that the technic of wound treatment given in no way interferes with aseptic technic. The original article must be read by those interested, as it scarcely lends itself to abstracting.

94. **Volkmann's Ischemic Paralysis.**—Sayre reviews the literature of the development of our knowledge on this subject, and says that the typical cases are almost all the result of fractures of the upper extremity, the great proportion being the bones of the forearm, and almost all in children. It commonly results from pressure applied in treatment. The Es-march bandage is responsible for many cases. The pain is often severe. The prognosis is grave and depends largely on

the amount of injury to the muscles. Electricity and massage have proved almost universally useless in restoring vitality. He describes the operative procedures.

96, 98. Abstracted in THE JOURNAL, Feb. 6, 1909, pp. 496, 497.

97. **Thorax Transfixion.**—Hyland reports a remarkable case of a man of 38, who, while operating an edging machine, was struck in the chest and thrown unconscious to the floor by a piece of "edging" which was found protruding from both sides of the body. It was part of a rough board, 1 by $\frac{3}{4}$ inch at the end which entered the body and 1 by $\frac{1}{4}$ inch at the other end, and 23 inches long. It entered the chest through the left nipple, breaking the rib and depressing it, punctured both lungs, and passed through the arm about three inches below the shoulder joint, posteriorly to the humerus, pinning the arm to the body. The man was taken 50 miles by train to St. Elizabeth's Hospital, Utica. He had recovered consciousness and was perfectly conscious up to the administration of the anesthetic. Hyland enlarged the openings, and with a great deal of force drew the edging loosely (? sic) through the body in the direction in which it had started. The resulting hemorrhage was insignificant. The right lung collapsed below the seat of injury. On inspiration and expiration, the air passed freely through both openings. Free drainage by gauze and tubes was installed. The highest temperature recorded was 102.2 F. on the second day. At no time were there any pronounced symptoms of pneumonia. An eighth of a grain of morphin gave relief from the pain. Traumatic pleuritis on the right side set in, ultimately becoming empyematous, but with the well-established drainage it ran an uneventful course, and the man returned home ten weeks after the injury, the wounds having nearly healed. He suffered at first intensely from pain and swelling in the arm, which he was unable to move. The forearm extensors were paralyzed, but he has now regained his usual health and vigor. A photograph of the edging in the body before removal accompanies the article.

- 104 Major Emergency Operations with Reference to Fracture of Skull and Wounds of the Abdomen. W. I. Terry, San Francisco.

99. **Intestinal Obstruction.**—Levison discusses acute and chronic bowel obstruction and on the basis of an experience with a large number of patients treated by the various methods in use emphasizes the fact, that those treated with most success were those operated on early and in whom he has not hesitated to explore the abdomen after the diagnosis has been established. If the obstruction is easily and quickly found, all that is done is to open the distended loop, express the intestinal contents and perform an enterostomy as follows: Two sharp hemostats grasp a spot on a loop of distended intestine, the beaks being in juxtaposition. The intestine is then opened by a knife puncture between the two points; the loop of intestine, having been drawn out of the abdominal cavity, is held close to a basin, so that the fluid can escape from the gut without any soiling of the abdominal cavity. As clamps are attached to the loop or gut, there is no possibility of the intestine escaping back into the abdominal cavity, and the opening, therefore, is under absolute control. This opening may be closed with a purse string suture or an enterostomy can be made. He has treated a number of patients, seen early, in this manner and intends to continue the method, as it is rational, simple and easily carried out without much shock. Drugs, such as atropin and eserine, in his experience, have been of no avail.

100. **Indian Practice.**—Grinnell's paper is an interesting folklore article drawn from his experience among American Indians. The methods of the quack indicate as high a degree of civilization among them as among ourselves. He pays particular attention to child-birth and the existence of a period of isolation for menstrual uncleanness.

106. Tetanus.—Doland, after discussing the bacteriology and pathology of tetanus, reports cases and considers the various methods of treatment of recent suggestion. He recommends the opening and closing of all punctured wounds and the use of tetanus antitoxin in suspicious cases and all fourth of July wounds, together with a 2 per cent. solution of magnesium sulphate, preferably by intraspinal injection. Should these measures fail, Bacelli's carbolic acid injections should be used. If the magnesium sulphate does not subdue symptoms he advises giving large doses of chloral, and finally stimulates the patient, preferably with whiskey, and shuts out all external stimuli to nervous excitation.

107. Industrial Eye Injuries.—Johnston divides the injuries, in a territory devoted to agriculture, lumbering and mining, into the following four classes:

- 1 Those occurring as the result of handling high explosives in mining and railroad construction
- 2 Those occurring from the bursting of locomotive oil and water gauges
- 3 Those occurring in mills, foundries, machine shops, and the building trades
- 4 Those occurring in the agricultural pursuits.

He discusses each class separately, with analysis of cases. The majority of these injuries are preventable, and he advocates: (1) Government inspection of the manufacture of all explosives; (2) licensing of "powder men"; (3) protection of water and oil gauges by wire or plate glass screens; (4) the placing of guards on all emery wheels, lathes, etc.; (5) education of the laity as to the seriousness of even slight injuries when infected.

112. Relation of Medicine to Other Professions.—McWhorter discusses the changes that have been brought about in the practice of medicine by those of environment, the crowding of population in the cities, the discoveries of science, etc., and considers the relation of the physician with the lawyer, the press, the legislature, the engineer, the educator and the social economist. He particularly contrasts the results of the old French Canal Company at Panama, with its disregard and ignorance of hygienic conditions, with those of the brilliant, hygienically conducted enterprise of Colonel Gorgas, and remarks that "the adverse forces of Nature may be scientifically controlled; they may not be ignored." To the general practitioner McWhorter says: "Do not misapprehend the dignity and importance of your efforts because of the humble station in life of your patients. The country doctor whose homely science restored Abraham Lincoln to health in boyhood days, probably made a larger contribution to the needs of humanity than did the brilliant surgeons who operated on Napoleon III or the Emperor Frederick. It might be well to remember this, gentle men, as you sit at the bedside of some bare ankled girl or some freckle faced boy. Only a large perspective reveals the true relations of things."

1. Rheumatic Fever.—In the third Lumleian lecture Moore sums up the points which in this course of lectures he has endeavored to impress on the profession at large as follows: (1) Rheumatic fever is a single definite disease; (2) endocarditis is always an essential part of it; (3) its duration may extend over many years, and these circumstances, but half demonstrated as they necessarily are at present, are still the safest indications of method in the treatment of the disease.

2. Gallstones.—Waterhouse discusses the causation, the symptoms, results and the prognosis of gallstones. His firm belief is that the majority of flatulent dyspeptic women who attend medical out patient rooms with such wondrous regularity are really suffering from gallstones. Jaundice is the exception in gallstone, save when the stone is impacted in the common duct. We must distinguish between (1) inflammatory—i. e., microbic—jaundice, such as may result apart from cholelithiasis, e. g., as a sequel of cholecystitis; and (2) lithogenous jaundice, which is, at first, at any rate, a mechanical process due to blockage of the common duct by a calculus. Biliary colic is the most prominent trouble, but most patients do not complain of it, because the gallstones commonly remain in the bladder and do not enter the duct. Vomiting is a fairly frequent symptom and a usual one in biliary colic. During an attack of biliary colic the liver may be swollen and the gall bladder exceedingly tender. In treatment, besides morphia and hot fomentations, Waterhouse is convinced that antipyrin, 10 grains every hour until 40 grains have been taken, is a useful drug. The administration of chloroform and massage of the gall bladder he recommends with confidence, but only when all signs of inflammation are absent. He next discusses permanent obstruction of the biliary duct and infective cholecystitis. The most frequent causes of death are (1) microbic cholangitis; (2) perforation of the gall bladder and ducts; and (3) carcinoma of the gall bladder. He insists on promptness of operative intervention as soon as it appears indicated. He is convinced that an early cholecystotomy is a satisfactory operation and far less dangerous to the patient than the passage of a single stone *per vias naturales*; on the other hand, he knows none more difficult than choledochotomy or extraction of a stone from the common bile duct in a long-standing case.

4. Alcohol Injections in Neuralgia and Spasm.—Harris discusses this subject in relation to trigeminal neuralgia, chronic facial spasm and sciatica. He describes in detail the technique for trigeminal neuralgia, and is of the opinion that this method affords certain relief. It is also of great service in controlling chronic facial spasm, postinfluenzal supraorbital neuralgia, the facial pain of inoperative carcinoma of the tongue, tabetic neuralgia, etc.

8 *Bilharzia Haematobia.—Allen contends that the entrance of the parasite is principally effected during bathing, and in his experience he believes that in the majority of instances the invasion took place through the urethra alone, but it is possible that it may enter the intestinal canal by the anus, or the lungs by infested water being sniffed in, but wherever it is found it has got to its final resting place directly from outside and has not reached it from the vascular system. The parasite undoubtedly does enter the stomach in drinking water, but it appears fairly certain that the gastric juice destroys it. The great majority of those infected are boys under the age of puberty, which fact he attributes partly to their greater bathing habits, partly to the ease with which the parasite can enter the urethra before the prepuce is retracted. During the act of bathing, the sac formed by the prepuce becomes filled with water, and a parasite would therefore have moisture, guidance, protection and time, every thing in fact to enable it to seize on a position so suited to it. He endeavored experimentally to establish the fact that the

parasite can not develop within the body, but must enter it in the mature form from without. With the consent of a patient, he injected many eggs of the parasite containing vigorous embryos into the bladder of one of the Indian hospital attendants. The man did not become affected, and remained at the hospital for some years, perfectly free from the complaint. This condition adds immensely to the importance of preventing it from entering the system. He considers it likely that the origin of the practice of circumcision in Egypt, as shown in sculptures dating 2,000 years before the captivity of the Jews, was really a sanitary measure, possibly directed largely against this particular infection. He insists on the importance, when bathing, of wearing close-woven drawers fitting tight round the waist and thighs, and not open anywhere; and also of drying the body thoroughly, particularly about the orifice of the urethra, on leaving the water. These measures, with circumcision, he believes would stamp out the disease in bilharzia infected regions, as the ova can not develop in the body.

15. New Chemical Tests in General Paralysis and Tabes.—

Ross and Jones review our present knowledge concerning the cerebrospinal fluid in general paralysis, and describe two new diagnostic chemical tests for readily recognizing an excess of globulin in the cerebrospinal fluid, thus determining the presence of some parasyphilitic affection of the nervous system. It is essential to be sure that no blood or pus has contaminated the fluid to be examined. The tests are as follows: The Noguchi reaction consists in the addition of 0.5 c.cm. of a solution of 10 per cent. butyric acid in normal sodium chloride solution to 0.1 c.cm. of the fluid to be examined; the application of heat; subsequent addition of 0.1 c.cm. of 4 per cent. sodium hydrate solution, with a further application of heat. The test tube should be read within three hours. A distinct opalescence is frequently found to occur, even in the normal, but in cases of general paralysis and tabes a characteristic precipitate of a peculiar flocculent character forms. The flocculi tend gradually to fall, so that after 24 hours at the latest the bottom of the tube is occupied with a fairly bulky precipitate, while the supernatant fluid is clear. In performing this test care must be taken to ensure the absolute purity of the butyric acid. The second test referred to is as follows: Two c.cm. of a saturated solution of ammonium sulphate are placed in a test tube, and 1 c.cm. of the cerebrospinal fluid is gently run on to the surface in the way done in the Heller nitric test for albumin. The formation of a ring at the junction of the two liquids constitutes a positive reaction. The ring is clear cut, thin, grayish-white, and has the thickness of a thin piece of paper. It should form within three minutes, and within half an hour it may be observed that the surface of the ring shows a delicate mesh appearance resembling a fine cobweb. Indirect illumination must be used, or it may escape detection.

The Noguchi test was applied in 15 syphilitic cases and 12 non-syphilitic. It was negative in all the latter except in one case of tuberculous meningitis. Among the negative cases were 5 of dementia præcox and 4 of tumor cerebri, conditions which are frequently difficult to distinguish from general paralysis. Among the 15 syphilitic patients were 12 untreated and 3 had been treated. None of the latter gave a positive reaction, while all the former did so. The 12 positive cases comprised 3 of tabes, 5 of general paralysis, 1 of tertiary syphilis, and 3 of syphilis of the nervous system. The test was thus positive without exception in all the cases of syphilis or parasyphilis in which the patients had not had recent

treatment, and negative in all other cases examined. The ammonium sulphate ring test was applied in all the above cases, except 2 of tabes. The results agreed absolutely with those obtained by the Noguchi test, being positive whenever this was positive and negative whenever this was negative.

- 20 Oatmeal in Treatment of Diabetes Mellitus. C. von Noorden.
- 21 Treatment of Gonorrhea in General Practice. J. E. McCracken.
- 22 Iodin in Treatment of Disseminated Sclerosis. W. Murrell.

19. Effects of Surgery in Mental or Nerve Disturbances.—Alexander relates five cases representing several classes of mental and nervous disease in which cure was effected by operative intervention, illustrating the following facts:

1. The mysterious effects of pressure on the heel in producing insanity, and its immediate cure when the pressure was removed.
2. The direct effects of a depressed fracture of the skull on the onset of acutely maniacal symptoms and the immediate relief through the elevation of the depressed bone.
3. The presence of a retroverted uterus in a case of delusional suicidal insanity, and the good effect of the cure of the displacement on the insanity.
4. The baneful influence of metrorrhagia on the mental state and the probable rescue of the patient from a lunatic asylum by operation.
5. The failure to connect as cause and effect a lipoma of the back and intense intercostal neuralgia, and the complete cure of the patient by operation.

In regard to the question of operating, therefore, in mental and nervous conditions, Alexander considers intervention indicated in cases in which the condition of the patients is beyond their control, and not in that class in which the patient will refer to his "terrible agony" with a placid face. The really suffering patient does more writhing in agony than talking about it. In the second place, Alexander holds that if there is a distinct disease that ought to be treated in an ordinary sane individual, and if that disease occurs intercurrently in mental disturbance of unknown causation and acute character, then that disease should be treated, and can be treated successfully notwithstanding the mental condition, and with the hope that the mental symptoms also may be cured.

- 26 *Rice and Beriberi. W. Fletcher.

26. Beriberi.—Fletcher describes the various modes of examination used at the Kuala Lumpur Lunatic Asylum. He points out that in communities where beriberi occurs, those who eat "cured" rice appear to escape. This "cured" rice is a yellow rice prepared as follows: The unhusked grain or paddy is soaked in water for from twelve to twenty-four hours, or even longer. It is then heated in vessels containing water over a slow fire until the husks burst. The third stage in the preparation consists of spreading out the grain and drying it in the sun; when this has been completed, it should be possible to separate the husk from the seed by light rubbing between the palms of the hands. The rice is then husked by pounding or taken to the mills, where the same process is effected by the millstone, but it is not polished by the rapidly revolving stones against the fine wire gauze after the manner of the "white rice." Fletcher considers it proved that the elimination of white uncurd rice from the diet prevented the occurrence of beriberi in the "cured" rice group of patients at the Kuala Lumpur Lunatic Asylum, and he recommends the adoption of this rice and the avoidance of the highly polished white variety, no matter how good the quality.

30. **Transitory Hemiplegia.**—Edgeworth reports four cases of transitory hemiplegia in elderly persons, and says that on consideration of these cases, it is seen that temporary attacks of aphasia, or aphasia and right hemiplegia, or left hemiplegia, or vertigo, or mental confusion, may be associated with (1) no arteriosclerosis, no general hypertonus, no rise in blood pressure; or (2) arteriosclerosis, but no general hypertonus or rise in blood pressure; or (3) arteriosclerosis, general hypertonus, and rise in blood pressure. The theory of a localized hypertonus, an arterial spasm, in cerebral blood vessels affords an adequate explanation of these various cerebral phenomena. It accounts for their often sudden appearance and for their equally sudden and complete disappearance. Such arterial spasm may be limited apparently to one or more cerebral arteries, or may form a part of a more general vascular constriction. In the latter case, it must be supposed that it is more marked in cerebral than in other arteries. Such a theory may be supported by the facts that (1) localized arteriospasm may occur in parts of the body other than the brain; (2) in some cases the paralysis may be preceded by chronic spasm in the subsequently paralyzed limb or the attack may consist of chronic spasm only, resembling the unilateral chronic spasms producible by digital pressure on one carotid; (3) a striking parallelism between the state of the radial artery and the cerebral phenomena; (4) the discovery of vasoconstrictors in cerebral arteries discloses a path for the passage of impulses, which may pass through these fibers. The accurate diagnosis of such cases is important, lest they be mistaken for cases of cerebral hemorrhage or thrombosis. Vasomotor dilators will rapidly effect a cure in a case due to vascular spasm, but they constitute the worst possible treatment for cases of thrombosis or hemorrhage. With regard to the tendon jerks and skin reflexes, all that can be said is that if the plantar reflex is extensor in a case of suddenly occurring hemiplegia, the cause is organic; if not extensor, the disease may exceptionally be organic, or it may be due to vascular spasm. A similar uncertainty attends any deduction drawn from the state of the tendon jerks. The onset of hemiplegia due to vascular spasm is usually unattended by loss of consciousness, but loss of consciousness does not always occur in hemorrhage or thrombotic cases. Hemiplegia due to vascular spasm is in some, but not all, cases attended by a rise of blood pressure. The differential diagnosis of the first attack of hemiplegia is therefore difficult. Recurrent cases of vascular spasm may end in permanent palsy due to cerebral softening. The administration of vasodilators in quantity sufficient to make the pulse soft, rapidly cures the spasmodic form, and probably postpones the day of permanent paralysis.

31. **Acute Appendicitis.**—Maylard investigates the following questions: 1. Should aperients or sedatives be administered in the early stage of the attack? 2. Should heat or cold be applied locally? He concludes that the early stage of acute appendicitis is best treated by (1) the administration of small doses of saline aperients—one dram of magnesium sulphate every hour till the bowels move; (2) the local application of heat to the iliac region; (3) the subcutaneous injection of a small dose—say 1/6 grain—of morphin, for the sole purpose of relieving the immediate acuteness of the pain.

32. **Arterial Blood Pressure in Arteriosclerosis.**—As the result of comparative investigation in cases with and without arteriosclerosis, Williamson concludes that the main difference between the arteriosclerotic and the non-arteriosclerotic cases would seem to be that there is produced in the former, owing to an abnormal degree of arterial constriction, as the

result of influences which diminish this constriction and produce vascular relaxation, a more marked effect than usual, and, in consequence, either a greater fall of pressure, or a fall of pressure when in the non-arteriosclerotic cases there would be a rise. This difference is evidenced more especially in the diurnal variations, but also to a less degree as the result of the ingestion of food.

33. **The Rheumatic Infection.**—Telling discusses the theory of rheumatism in relation to other affections that are commonly considered rheumatic. Rheumatism is essentially a disease of childhood and early adult life. He describes the mental and physical type of the rheumatic child, who has long lashes, clear, bright-colored complexion, hair not infrequently reddish or auburn, and is "pretty"—possessing certain refinement and delicacy of features. He does not believe that iritis occurs as a manifestation of rheumatism; it is generally due to gonorrhea, syphilis or gout. He discusses the arthritic phenomena, chorea, the heart lesions and the skin lesions, particularly erythema nodosum, the organic connection of which last with rheumatism he doubts.

34. **Labyrinthine Nystagmus.**—McKenzie sums up his investigations as follows:

1. When destructive processes cause perceptive deafness they generally cause a proportionate amount of damage to the vestibular organ of equilibrium.

2. An exception to this rule is found in otosclerosis, in which the amount of loss of hearing seems to bear but little relation to the amount of impairment of the vestibular sense.

41 The Newer Microbiologic and Serologic Means for Diagnosing Syphilis. C. Levaditi. Commenced in No. 2.

40. **Fluxions and Alternations in Disease.**—Brocq applies the term of *poussée fluxionnaire* to the element in pathology which determines the outbreak of symptoms in certain cases. The simplest form is the reaction which follows the ingestion of some substance which the organism is unable to tolerate; there may be a rash or gastrointestinal disturbances or both as the manifestation of the reaction to the disturbing substance. The individual susceptibility, generally inherited and familial, decides the nature and intensity of the reaction. Gout is a typical example of the other form of the *poussée fluxionnaire*: After a longer or shorter period of freedom from symptoms, the explosion occurs apparently spontaneously. In both these forms it seems that the intoxications and auto-intoxications of the organism, defective functioning of certain viscera, state of the nervous system, etc., pile up to induce a condition in which the slightest occasional cause may supply the spark and induce the explosion, the fluxion, the wave of congestion; and the wave flows to the point of least resistance at the moment. This point of lesser resistance determines the localization of the symptoms in each individual case, but this point may vary each time. This assumption throws light on many otherwise inexplicable morbid and therapeutic phenomena.

April, XXVI, No. 4, pp. 197-276

42 *Treatment of Pernicious Vomiting of Pregnancy. (Traitement des vomissements incoercibles de la grossesse.) V. Wallich.

42. **Pernicious Vomiting of Pregnancy.**—Wallich recommends isolating the patient in the care of a nurse and abstention from anything by the mouth for twenty-four or forty-eight hours. Fluids may be supplied by enemas of physiologic salt solution or possibly by very cautious subcutaneous injections. Drugs must be given prudently on account of the insufficiency of the emunctories, giving the preference to chloral by the rectum and to inhalation of oxygen. The diet can be regulated as tolerated, first nothing, then water alone, then half milk, gradually returning to a full milk-vegetable diet. Pinard advises interrupting the pregnancy as soon as the pulse rate is over 100 or keeps permanently about 90, even if the amount of urine approximates normal, if the incessant vomiting and the nervous symptoms persist unmodified.

44. Pathogenesis of Amyloid Degeneration of the Kidneys.—In connection with a case of purulent pleurisy accompanied by intense albuminuria, Castaigne discusses the effects produced on the organism by an alien albumin introduced into the circulation. The injected albumin retains its alien characteristics wherever it is resound in the blood; the organism discriminates between the albumin that belongs to it and the alien albumin and retains the former while striving to get rid of the latter. The pus in purulent pleurisy contains large amounts of alien albumin, and if the plasma retains its normal absorbing power, this alien albumin is absorbed into the blood and is eliminated through the kidneys. The absorbing power of the plasma is much reduced in pneumococcus and tuberculous affections, but seems to be retained unimpaired in streptococcus pleurisy. The alien albumin is thus absorbed and is liable to injure the arteries on its way to the emunctories. The kidneys are overtaxed by this extra work imposed on them and the parenchyma suffers sooner or later. The resulting amyloid degeneration of the kidneys is always accompanied by chronic nephritis from the same cause, but the kidneys retain their permeability. Consequently, there is no necessity for restricting the proportion of nitrogen in the diet. These patients need food rich in albuminoids to compensate for the losses of nourishing materials, avoiding merely sodium chloride and albumins difficult of digestion; such as raw white of egg. The prognosis depends on whether the purulent process is acute or chronic, as in the acute cases, without cachexia, the tendency is for the amyloid degeneration to subside in time after the cause is removed. On the other hand, an acute process may entail the severest changes in a few weeks. He found amyloid degeneration of liver, kidneys and spleen in three patients who had succumbed in three, four and six weeks to purulent pleurisy.

46. Orchitis and Epididymitis in Staphylococcus Septicemia.

—In a case described the *Staphylococcus aureus* was cultivated from the blood of a previously healthy man of 34 presenting signs of severe general infection about a week after development of a carbuncle on the back. He was convalescing a week later when signs of inflammation of the testicles and epididymis were observed and the staphylococcus could also be cultivated from the puncture fluid. The organism seeking to get rid of germs tries to eliminate them not only through the liver and kidneys, but also by the glands, which explains the orchitis in certain affections. Roger found the testicles involved in 48 of 55 smallpox cadavers in 1901-2. The orchitis, parotitis and tonsillitis in certain diseases, such as mumps and smallpox, are not complications, but localizations of the infection. Quénu has been unable to find any case on record, however, in which orchitis was recorded in

connection with a primary staphylococcus septicemia in the absence of methitis.

48. The Red Corpuscles as the Receptacles of the Antibodies.—Bergeron presents and discusses the conceptions on which Spengler bases his treatment of tuberculosis. The latter assumes that the tuberculous individual is almost invariably infected with both human and bovine tubercle bacilli, and that treatment should be directed against both. He also insists that the red corpuscles are the principal receptacles for the antibodies, not the serum. The antibodies pass into the serum only when the red corpuscles become destroyed and they stay free in the serum only a very short time as they are rapidly taken up by the leucocytes. Consequently, Spengler asserts, specific treatment of tuberculosis should be by means of the red corpuscles of animals which have been powerfully immunized against tubercle bacilli of both types, human and bovine. The red corpuscles of these animals contain the antibodies, agglutinins, precipitins, bacteriolysins and antitoxins needed for effectual treatment of the infection, and by isolating and dissolving the red corpuscles we have a preparation, the Spengler I. K. (*Immunkörper*) which seems to be giving highly encouraging results in the clinic. Bergeron's own experience with it has not been sufficient for definite conclusions, but to date his results confirm the statements of others in regard to the frequent benefit even in the advanced and the clinical cure in the mild and moderate cases.

55. Arrest of Hemorrhage in Palliative Operations on Cancerous Uterine Cervix.—Instead of curetting, de Bovis amputates the lower part of the cervix, keeping inside the limits of the cancerous tissue, believing that the smooth surface left is an improvement over the ragged results of curetting. To ensure hemostasis or arrest hemorrhage he clamps with narrow bladed forceps the wall of the cervix in the groove made preliminary to the amputation. The results have been very good. In one case a young woman survived for a year at least after this palliative amputation. It obliterates the vessels in the cervix and leaves a smooth wound which oozes very little. The Museux forceps used for the purpose are generally left in place for a day or two, but may be left for a week without inconvenience.

56. Experimental Tuberculosis with Cavity Formation.—Romer relates experiences which show that guinea-pigs previously rendered tuberculous respond to a severe new infection by production of cavities in the lungs. Animals with chronic tuberculous processes display exceptional resistance to new tuberculous infection, and the appearance of cavities in the lungs seems to be thus to a certain extent an immunity phenomenon. In long series of experiments the guinea-pigs all developed this tendency to cavities in the lungs under the same conditions with great constancy, thus confirming the assertions of von Behring and Orth in regard to the produc-

tion of cavities. The facts observed suggest also that in the majority of cases of pulmonary tuberculosis in man the disease is a reinfection from some old tuberculous process elsewhere—a metastatic autoinfection.

57. Cosmetic Operations.—Holländer gives illustrations of a number of cases of deformity of the nose or breast, causing much disfigurement, which he was able to correct with gratifying results. In one case paraffin injected to fill out the breasts had settled into knobs adherent to the skin and very disfiguring. He made a circular incision in the mamilla through which he was able to scrape out the twelve paraffin bunches without a visible scar and with excellent results. In other cases he filled out shrunken breasts with a mixture of human fat and mutton tallow. The absorption proceeded more slowly and the reaction was the more intense the smaller the amount of human fat in the mixture. The effect a year later was excellent in every instance; the human fat was obtained from excised lipomas. In another case disfiguring hypertrophy of one breast was remedied by turning back the breast from a long incision below and scraping out about 2.2 pounds of the breast tissue, which was found in fatty degeneration. The breast was then replaced, pushing it up to be on a level with its mate, cutting out a strip of superfluous skin below, about 3 cm. wide. He recommends this operation even for bilateral hypertrophy. He has been able to remove glands in the neck even down to the chin through an incision above the edge of the hair and thus invisible. Tumors in the brow were removed through a small incision in the eyebrow. By applying superheated air to wounds after suture, the epidermis on each side is mobilized for a little distance without injuring the suture or ligature. When the edges of the wound meet without the least tension the resulting scar is practically invisible, and this is ensured by the application of superheated air. His experience with paraffin in the treatment of deformity of the nose has been disappointing. In case of loss of the bridge of the nose he cuts out the bone and turns the flap over downward, in such a way that the skin of the nose forms the under lining and the bone the support for the tip of the nose. He then draws down from the brow a flap of skin and forms the nose of it. If there is too little bone he implants one or more slices from the tibia. By this technic the tip of the nose has a most natural aspect. The transplantation of a piece of the tibia has many advantages. Some of his rhinoplastic operations were done eight or ten years ago, and the new-formed nose has proved its permanency and cosmetic appearance. He generally works from within the nose to save a scar.

59. Rachitis from Lime Starvation.—Schabad remarks that the deficit in lime may result from inadequate intake or from defective absorption with normal intake. Breast milk may be deficient in lime, and it is important, he says, to note the lime contents of breast milk, as well as its proportion of fat, albumin and carbohydrates. It is possible that a preparation of lime, phosphorus and cod-liver oil might increase the retention of lime, although in his experience no benefit was derived from them except in rachitis. It is important to change the wet nurse in case the lime content of the breast milk can not be kept normal. If cow's milk is given it should not be diluted too much, giving at least one-third milk. The slightest deviation from normal in digestion or the digestive tract should be promptly treated to ward off disturbances in the intestinal functions which might affect the lime metabolism unfavorably. Rachitis due to lime starvation is liable to induce clinical phenomena more readily than true rachitis, but severe rachitic disturbances in a child exclude the pseudo-rachitis from lime starvation. During the onset of rachitis there is increased elimination of lime and phosphorus, the latter predominating, but in pseudo-rachitis from lime starvation the elimination of lime predominates.

61. Differential Stain for Tubercle Bacilli.—Gasis' stain is based on the property of tubercle bacilli to resist the action of alkalis. He regards this "alkali-proof" condition as the only property peculiarly restricted to tubercle bacilli. Smegma bacilli, etc., are not "alkali proof."

64. Pathology of the Large Intestine.—Rosenheim demonstrates that the different segments of the colon have a peculiar independence in both normal and pathologic conditions. There may be localized disturbance in the functions, causing retention of feces in the segment involved. Obstinate constipation may occur localized solely in the sigmoid flexure or at some point in the colon. The diagnosis requires palpation of the large intestine during the period of constipation. He allows the patient to go for two or three days without a passage, in order to examine instructively the large intestine in detail. This is the only way to learn the exact condition in the bowel and the seat of the disturbance as a guide to treatment. The comparative emptiness of the segment of the intestine below the point is instructive. These localized disturbances are sometimes the most distressing symptom of a general neurosis or they may reveal some affection in adjoining organs.

66. Analysis of the Excito-Inhibiting Mechanism of the Stomach Glands.—This article is supplementary to Bickel's, summarized in these columns, page 1800. The details of the experiments and metabolic findings in the dogs with "nerveless" blind pouch stomachs are tabulated and compared.

67. Blue Arc Light in Treatment of Wounds and Leg Ulcers.—Richter claims that an ordinary arc light with reflector and blue glass screen has the same healing action as sunlight, and that it has a powerful influence in promoting the healing of granulating and suppurative wounds and leg ulcers. It cleans up the infected and dead masses, stimulates the production of granulations and the growth of epidermis, and relieves pain and makes cauterization, powders and salves unnecessary. The scar left is more elastic and resistant, softer and painless. All this is the result of the direct influencing of the arterial blood supply and of the stimulation thus provided for the regenerating tissues.

70. Improved Tests of Pancreas Functioning.—Müller has applied to the stools his method of determining the proteolytic action of a ferment by the eating out of a hole in solidified serum on which the drop containing the ferment has been deposited. This dimpling (*Dellenbildung*) reveals the proteolytic strength of the ferment in the drop and the absence of dimpling shows that the ferment is absent or inactive. A drop of thin stool causes dimpling or not according as it contains pancreatic trypsin or not. The dimpling demonstrates that the pancreatic duct is permeable and that the pancreas tissue is functioning more or less normally. Negative findings indicate complete occlusion of the pancreatic duct or some severe disturbance in the secreting function of the pancreas. In his research, absolutely negative findings were never obtained except with organic affections of the pancreas, but it is possible that they might occur with purely functional insufficiency. This serum plate dimpling test is reliable but rather inconvenient for the general practitioner, and he has accordingly, with Schlecht, devised a still simpler method based on Sahli's test of pancreas functioning by having the patient ingest a "glutoid" capsule containing iodoform or salol. These capsules are hardened in formaldehyd and resist the action of the gastric juice and are dissolved only by the pancreatic juice. The appearance of the iodine or salicylic reaction in the saliva or urine indicates that the capsule has been dissolved. Positive findings after a certain interval reveal that the pancreas is probably functioning normally. Müller has simplified this test by transferring it from the living body to the test-tube. He uses a capsule hardened in an alcoholic solution of formalin, which dissolves readily in a fluid containing pancreas trypsin while resisting almost indefinitely the action of other organic fluids. The capsules used are filled with charcoal, and 10 or 15 c.c. (about a tablespoonful) of stool as thin as can be obtained is placed in a test-tube wide enough to allow the capsule to float in the fluid stool without touching the walls. The stool must not be filtered and the tube must not be heated above 98 F. If the stools contain the normal proportion of trypsin, the capsule will dissolve in about half an hour and the charcoal will stain the fluid, but if no trypsin is present the capsule will remain unaltered for a day or so before it finally dissolves. This method also permits quantitative estimation of the functioning by comparing the findings when the stool is diluted with 5, 10, 20, 50 and 100 times its bulk with a 10 per cent. aqueous solution of glycerin. Control tests with the serum plate dimpling method gave parallel findings in every case. The Gross method can also be applied as a functional test for the behavior of the pancreas. This is based on the fact that casein in an alkaline solution is readily precipitated by diluted acetic acid, while there is no precipitation if the casein has been subjected to the action of trypsin. The thin stool is mixed with three parts 1 per thousand soda solution and filtered. The test is made simultaneously with graduated amounts of the stool in a series of test-tubes containing each 10 c.c. of a solution of 0.5 gm. pure casein in a liter of 1 per thousand soda solution. For all the above tests the patient is prepared with an enema, fasting, then, after defecation, a test breakfast, followed by a little carmin or charcoal to limit the stools, and an hour or so later is given a purgative. A little chloroform is added also to the stool in the test-tubes to prevent bacterial action, and the stool used for the tests is the most fluid portion that can be obtained. He urges others to compare with the Cammidge reaction the findings with the serum plate and test-tube capsule methods as liable to prove exceptionally instructive, but does not mention any experience of his own in this line.

71. Jerky Respiration as Sign of Pulsating Aneurism.—Ortner reports a case which confirms the possibility of a disconnected respiration of a staccato type from the hammering of the trachea by an aneurism resting against it. His curves of the pulse and respiration reveal the mechanism and type of disturbance in question.

73. Coincidence of Epigastric Hernia and Gastric Ulcer.—Ury reports two cases and refers to four mentioned by Strauss and states that he has found three others in the records of Boas' polyclinic. There seems to be an unmistakable connection between the traction and disturbance resulting from an epigastric hernia and the development of an ulcer in the stomach. He warns further that the symptoms may be referred to the evident hernia, when in reality they are due to an unsuspected gastric ulcer. On the other hand, it is possible that symptoms ascribed to an assumed gastric ulcer may in reality be the work of an insignificant and overlooked hernia. In one of his cases the patient was a workman of 56 with inguinal, umbilical and epigastric hernia, and, finally, symptoms of gastric ulcer. Ury has advised operative treatment of the epigastric hernia, at least, in this case, hoping thus to improve conditions for the gastric ulcer.

76. Diuretic Action of Potassium Bitartrate.—Burwinkel, confirms from his own experience the commendation of potassium bitartrate, as a diuretic, from the pen of Eichhorst, summarized in these columns April 24, page 1369.

86. Self-Healing Processes in Brain Tumors.—Anton discusses the fact that tumors are liable to soften and become cheesy in the center, reduced in size and thus cause less pressure. He has also encountered cases in which hydatid cysts subsided and degenerated, and cases in which tumors became encapsulated with reduction in size. In some cases a spontaneous hemorrhage occurred in the tumor, checking its growth and followed by the absorption of the blood. The cerebral fluid may make its escape through the nose, or, as in one of his cases, through the orbit. He has witnessed excellent results from an artificial opening in the corpus callosum to permit communication between the ventricle and subdural space. This is an important aid in operating, to prevent hernia of the brain when the dura is incised. In four cases of this kind the severe symptoms subsided and the focal symptoms remained stationary. In a case described in detail, a large glioma in the cerebellum with hydrocephalus caused severe symptoms, but suddenly the headache became less, the respiration freer, the pulse more regular, and psychic improvement was also observed. The patient succumbed to pneumonia and autopsy revealed besides the glioma a blood-filled cyst on the other side. The hemorrhage had evidently caused the destruction and encapsulation of this tumor, the resorption afterward reducing the compression on the brain and thus improving the clinical picture.

87. Professionally Acquired Syphilis in Physicians.—Waelsch states that during the last ten years he has encountered in his practice at Prague six cases of professional syphilis in physicians, half of the total number of his cases of extragenital infection during that period. He remarks that it is a universal experience that the most remarkable cases, the rarest complications, and the most unexpected course of diseases are always encountered in physicians or their families. He mentions as a special example of this the chronic, non-gonorrheal urethritis which affects almost exclusively medical men and has a very bad prognosis, both as to its course and its permanent cure. In each of the professionally

acquired cases of syphilis, it is evident that the infection might have been avoided with a little care. The primary lesion was on the fingers in all but one case, its cause not suspected until the lack of tendency to heal and the appearance of glandular involvement aroused the suspicion of syphilis. There were no serious manifestations in any case, and no tertiary phenomena. He warns that the hands should be manicured cautiously, not pushing down the skin at the base of the nail, to avoid minute lesions. On the slightest suspicion of a defect in the protecting skin, a rubber cot or glove should be worn, after covering the defect with collodion or fluid plaster. Every patient operated on should be examined for syphilis, whether the operation is gynecologic, obstetric or general, and on suspicion of syphilis gloves should always be worn. Syphilitics should be warned of the necessity of informing the surgeon before any operation in regard to their syphilitic history, both in their own interest and in that of the surgeon. The syphilitic should always inform his dentist of his infection before his teeth are treated. In case the physician injures his hand while operating on a syphilitic, he must burn out the lesion at once with the actual cautery, or if the injury was made with the syringe needle, leave the needle in place and connect it immediately with the negative pole for electrolysis of the tissues around. Simple washing with a corrosive sublimate solution is not effectual here.

90. Influence of Streptococcus Infection on Leucocyte Blood Picture.—The findings in Zangemeister's ten monkeys showed a characteristic curve of the mononuclear neutrophils in the first twenty-four hours from which the further course of the infection could be foretold with absolute certainty. The polynuclears and the eosinophiles also showed a characteristic curve, but less pronounced. The mononuclears increased from 40 to 60 per cent. in the mild and from 45 to 67 per cent. in the moderate cases in the twenty-four hours, while in the fatal cases the mononuclears dropped abruptly from 45 to 42 per cent. If these findings in monkeys can be applied to man we have an easy method of determining the outlook in streptococcus infection in operative and obstetric cases. The leucocytosis ranged from 18,000 to 25,000 in the mild cases and from 17,000 to 13,000 in the moderate, while in the fatal cases the leucocytes dropped from 23,000 to 9,000 within six hours.

92. Temperature Relations Between Lungs and Heart.—Exner calls attention to the admirable provision for keeping the heart cooled that is afforded by its being imbedded in lung tissue which is constantly being cooled by the air inhaled. The heart has been estimated to produce 70 calories on an average during the twenty-four hours—an enormous proportion in relation to its size of the average 2,800 calories produced by the entire organism. It is protected against the evil effects of overheating during exertion by the inhaled air: during exertion the breathing is apt to be through the mouth, which brings the air more directly to the heart. Animals after running pant with open mouth and lolling tongue. He suggests that this provision for keeping the heart cool might serve as a guide to treatment of pathologic conditions in the heart.

93. Tendon Transplantation.—Aberle presents arguments to sustain his view that transplantation of tendons is superfluous in the milder cases of flaccid paralysis and useless in the severer cases. In the mild cases the benefit derived and attributed to the tendon transplantation is in reality due to the supplemental fixation, massage and manipulations correcting and overcorrecting the deformity. These should be given a thorough trial first, before tendon transplantation is even considered.

- 104 Prophylaxis of Hemophilia. (Weibliche Helden.) L. Pincus.

100. Disinfection of Rubber Gloves and Silk Catheters.—Heusner has found that rubber gloves can be boiled in glycerin as long and as frequently as desired. He has the disinfector made with an outer and inner chamber between the walls of which is a wire netting. The gloves are placed in a closed wire netting box in the bottom of the disinfector to keep them covered with the glycerin. The double walls and wire netting act like a safety lamp, allowing the penetration of the heat without danger of overheating. Numerous tests showed that the gloves were always sterile after heating to 110 or 115 C. for thirty minutes in this apparatus over a gas stove or alcohol lamp. Not a trace of injury or change was seen in any of the gloves, silk catheters and instruments thus sterilized. The only objection is the expense of the glycerin, but the same glycerin can be used repeatedly.

103. Coagulating Action of Placenta Tissue and Eclampsia.—Engelmann and Stade state that of 19 rabbits injected with filtered placenta juice in the most diverse concentrations and quantities, 17 died, generally in a few minutes. The fatal action of the placenta juice was evidently the result of excessive coagulating power. In another series of 13 cases the simultaneous or immediately preceding injection of a substance that checks coagulation saved the animals after the injection of placenta juice. Thrombosis developed in every case in which the injection of the coagulation-inhibiting substance was omitted or an inadequate amount injected. It seems evident that the placenta juice contains some blood-coagulating substance, and that it is possible to check its action by injecting some coagulation-impeding substance. The research reported included experiments on 49 rabbits and 31 white mice. The results apparently throw some light on the etiology of eclampsia.

108. Epidural Injections in Treatment of Enuresis.—Allasia has applied Cathelin's method of injection of salt solution in twenty-two cases of involuntary micturition at night in children, and obtained good results in about half the little patients. Examining these successful cases more closely he has become convinced that the effect was merely the result of suggestion, and that probably equally good results can be obtained by the usual measures supplemented by suggestion without the necessity for the epidural treatment. Children inclined to idiopathic enuresis are generally neuropathic and

frequently present physical signs suggesting degeneracy, and the tendency to emaciation generally improves under the influence of the stay in the hospital.

- 116 Fluctuation of the Phenol in the Urine in Certain Affections of Digestive Apparatus and Connected Glands (Oscillazioni del fenolo nelle urine in alcune malattie dell'apparato digerente e glandole annesse) T. Capparelli

112 Alleged Specific Changes in the Leucocytes in Purulent Inflammation.—Pavesi gives the findings in 92 cases of purulent inflammation, in 32 with other lesions without suppuration, and in 10 healthy individuals. He followed Ce-aris-Demel's directions but was unable to find these changes in the leucocytes so constantly as the latter and, on the other hand, he found them in some cases free from any suppurative focus.

114 Acute Decubitus After Stovain Spinal Anesthesia.—Bilancioni reports three cases in which men between 25 and 50, operated on under stovain spinal anesthesia, developed acute decubitus whose course, site and other characteristics left no doubt as to the connection with the toxic action of the stovain, the patients not being debilitated or bedridden. He discusses the origin and nature of these lesions, comparing them to the paralysis from the toxic action of the drug.

115. Pathogenesis of Certain Forms of Cirrhosis of the Liver.—Baduel ascribes the cirrhosis in certain cases to a primary chronic torpid peritonitis involving the liver by the lymphatic route. The same explanation applies also to certain cases of pericarditis, both cirrhosis and pericarditis being of lymphatic origin from some primary source in the peritoneum. The changes in the liver in these cases are too extensive to be referred to congestion alone, and his experimental re-earch has confirmed the assumption of a lymphatic route for direct communication between the peritoneal sac and the interior of the liver. A stain injected into the peritoneal cavity was found after eight or ten hours in spleen and liver, and in still larger amounts after twenty-four hours, while not a trace could be detected in the kidneys, lungs, heart or veins. This etiology of the disturbances in the syndrome described by Pick as "pericarditic pseudocirrhosis of the liver" is confirmed by the findings in two cases reported and the absence of other probable causes. One patient was a girl of 14, the other a man of 40, the autopsy findings in each case are compared.

118 Tumors at the Base of the Brain.—Rummo concludes his long study of the anatomic and physiopathologic aspects of tumors of the base of the brain with a tabulation of the various syndromes caused by tumors in the anterior, posterior or median portions of the cranial fossa and in the three subdividing zones in these parts. The article is accompanied by 61 illustrations the last one showing instructively the course of the various cranial nerves as they pass through this region and their liability to injury from tumors at various

points. A large number of personal cases with comparison of the clinical and autopsy findings are reported, some demonstrating anew how a tumor in the frontal lobe, by compression from above, may induce a "base" syndrome. The topography and nature of the tumor and the age of the patient are the criteria for treatment, and a course of antisiphilitic medication should be instituted even when there is nothing in the case to suggest syphilitic antecedents, unless the patient is to be operated on at once. A solitary tubercle, glioma or osteosarcoma develops much more slowly than a sarcoma or carcinoma the latter proving fatal generally in two years and in a few months in children. A cavernous angioma, however, may persist without fatality for a couple of decades and a tubercle may enter a stationary phase or even undergo retrogressive metamorphosis, ossification and calcification. Other things being equal, young individuals bear tumors at the base of the brain better than adults owing to the superior elasticity and yielding capacity of the bones and sutures of the skull. Operative treatment may give great relief from palliative puncture of the ventricle or lumbar puncture or resection of compressing bone, but he regards tumors of the base of the brain as beyond the reach of the surgeon for radical surgical measures.

119 Polynueritis from Chilling.—Mancini reports three cases of acute polynueritis for which no other cause could be discovered except exposure to cold and dampness. There was no fever in any of the cases and the patients recovered completely in from two to eight months. The Lasègue sign was pronounced in each case, that is, flexion of the thigh on the hip was painless. He discusses the literature on the subject and suggests that the chilling may induce the production of a cytotoxin specific for the peripheral nerve cells.

- 124 Sarcoma Treated with Coley's Fluid V. Hertel

- 125 Veinoma Method of Treating Hemorrhoids H. von Thun

122 Registration of Phases of Respiration.—Sonne has devised an ingenious little mask apparatus in which a constant current of air is forced through a tube to a Marey recording drum but with a gap opposite the mouth so that the current of air has to jump this gap to enter the wider continuation of the tube that leads to the drum. The current of air does this regularly jumping the gap without effort and continuing on its way in the tube except when the current is interrupted by the breath passing in and out from the mouth. These interruptions are recorded on the drum and thus graphically register the phases of respiration. He tabulates the findings in 25 healthy persons examined reclining and standing, during physical exertion and at rest, and discusses the influence of the varying types of respiration on the blood pressure, etc.

123 Influence of Emotions on Variations in Leucocyte Count.—Ellermann and Erlandsen examined the blood of fifteen persons, taking a fresh drop of blood every minute or so for four or five blood counts in each case. They found that the drop of blood obtained first always contained the largest number of leucocytes. The difference between the number in the first and the following drops sometimes amounted to 35.6 per cent., ranging from 3.5 to this percentage, although the interval between the first and the fifth drops was less than ten minutes in every instance. They ascribe the larger number in the first drop to the emotional shrinking from the insertion, believing that the psychic condition is able to influence the number of leucocytes in the peripheral blood by the same mechanism as in other physiologic variations in the blood count.

124. **Sarcoma Treated with Coley's Toxins.**—Hertel reports several cases of sarcoma in which such benefit was derived from injections of Coley's fluid that he regards it as a duty henceforth to apply it in every such case, especially after removal of a sarcoma, to prevent or attenuate recurrence. He describes three cases in detail. One patient was a man of 29, with sarcoma in the testicle, which was removed, as also a metastatic recurrence a year later. He was then free from recurrence for two years, but then two metastatic tumors in the pelvis required removal but only a partial excision was possible. The operation was supplemented by injections of Coley's fluid and during the ten months since there has been no sign of recurrence. In another case there were signs of a tumor in the spinal canal and the rapid development of symptoms suggested malignant disease. Nothing was found to indicate a primary cancer elsewhere, and, on the assumption of a possible sarcoma, a course of injections of Coley's fluid was instituted. As no improvement was perceptible after about a month, the tumor was sought and removed by a laminectomy. The peculiar appearance of the tumor suggested a fibroma more than sarcoma, but the physicians who saw it concluded that it must be a sarcoma which had been modified by the action of the Coley's fluid. He cites this case as showing that an intradural sarcoma could be so influenced by the injections that it was practically cured, all growth was arrested, and the tumor was modified almost beyond recognition. The patient might possibly have been spared the laminectomy with a little more patience.

125. **Vernon's Method of Treating Hemorrhoids.**—von Thun gives an illustrated description of Vernon's technic, summarized in *THE JOURNAL*, Nov. 2, 1907, page 1560, and states that he has applied it with gratifying results in ten cases of hemorrhoids. Among its advantages are the cleanliness of the technic, the rectum being shut off from the field of operation, the linear scar, and the freedom from danger of injuring the sphincter of the anus and tendency to stricture later.

- 129 *Diagnostic Importance of Lumbar Puncture. (Lumbalpunktionens diagnostiska betydelse, särskildt vid börjande paralytiska generala.) J. Billström.
126. **Serodiagnosis of Syphilis.**—Among the 200 persons tested, 41 were certainly not syphilitic, and a positive response to the test was obtained in this group only in a few lepers. The findings on the whole confirm those reported by other writers. Marcus has examined nearly 500 persons with similar conclusions in regard to the valuable information to be derived from the test, although, he remarks, it is not specific for the syphilis virus but for the disease itself and possibly for an entire group of protozoon affections.

128. **Connection Between Alcoholism, Diabetes and Changes in the Pancreas.**—Heijl describes the autopsy findings, with three illustrations, in a case of moderate diabetes in a man somewhat addicted to alcohol. The pancreas was found much degenerated; scarcely any of the Langerhans islands were normal. He is inclined to accept the opinion that the alcohol injures the pancreas and thus induces the diabetes, although the symptoms of cirrhosis of the liver may predominate during life. He urges systematic research in every case of alcoholism in respect to the condition and functioning of the pancreas.

129. **Diagnostic Importance of Lumbar Puncture.**—Billström summarizes sixteen cases of general paralysis in which the cerebrospinal fluid was examined, the findings confirming the value of lumbar puncture in psychiatry. The globulin reaction is particularly instructive; it was positive in 100 per cent. of 34 cases of general paralysis, and the simplicity of the test commends it for general use, according to the technic of Nonne and Apelt for fractioned precipitation of albumin.

Address

RELATION OF THE PHYSICIAN IN PRIVATE PRACTICE TO THE PUBLIC HEALTH *

WALTER WYMAN, M.D.

Surgeon-General, U. S. Public Health and Marine-Hospital Service
WASHINGTON, D. C.

Before entering on details or discussing the more practical phase of my subject, it will be of interest, I trust, to consider briefly the relation of the public health movement to the general welfare and to the still broader theme of human progress.

SCOPE OF THE PUBLIC HEALTH MOVEMENT

Human welfare may be described under three heads: physical, mental and spiritual. These three elements are correlated, each bound closely with the others, and together they represent the scope of all human endeavor. Without minimizing in the least the other two, it seems to me that at the present time our principal needs relate to the physical.

Physical welfare is the foundation of race welfare in its broadest sense. It may be likened to the Constitution in our legal system. The Constitution is the foundation of our laws. There is not a state law, or a city ordinance, or police regulation, that does not rest on it or is not in conformity therewith, unless it be one that is voidable. Yet we think little about the Constitution, as we are enacting or enforcing our local ordinances, because we take the Constitution as a matter of course, or because it is so intimately connected with our political system that it requires no special thought.

Again, we look on the beautiful dome of the national capitol at Washington, and the legislative chambers beneath, and have scarcely a thought of the foundation on which it all so securely rests; yet it is there, and without it the dome and the chambers could not meet our vision. So physical welfare seems to me to be the necessary foundation for the general welfare; and we should so perfect it that we may lose sight of it and give our contemplation and efforts to higher welfare. In other words, physical welfare is only a means to welfare on a higher plane.

A sound mind in a sound body, *mens sana in corpore sano*, is an aphorism that has come down to us from antiquity, expressing both a truth and a goal to be attained; but in the light of modern thought it is insufficient as a guiding sentiment, since it contains no mention of the spiritual, and this latter is included in the modern thought of human progress.

Just what human progress is, just what it means, can not be defined. Writers of the day speak frequently of the uplift of the race, but there is no definition in this term; and yet, without understanding it, there is no doubt that we are all engaged in furthering human progress, in the uplift of humanity.

There is in astronomy what is known as the true stellar motion. By this is meant that, while the stars are revolving in their orbits, and the planets are also revolving on their axes, and some stars seem fixed, there is a general movement of them all, a progress through space; whither they are going and whence, we do not know, but we do know they are moving. So with human progress and the uplift; it exists. We do not understand it, and the best we can do is to catch its trend and keep ourselves in proper relation to it.

In this movement, the private physician endeavors to keep the individual in line—in his correct place as an individual in the ranks of humanity, as humanity is pressing forward to its destination. If the individual weakens, or meets with accident, the physician discovers the cause of the weakening and applies the remedy, or applies his surgical skill to repair the results of accident.

Analogous service is rendered by the lawyer, whose ideal function is to preserve justice in the ranks; and by the minister of the gospel or priest, who promotes morality and spirituality, these also being essential to human progress.

The physician, then, while ministering to the physical, is also contributing to the mental and spiritual, performing his part as others are performing theirs, absolutely necessary for the general welfare, yet only one of several units.

I fear that these somewhat abstruse thoughts may fail to interest, but I have endeavored to ascertain just where the physician stands in the realm of humanity—what is his relation to the world's work and progress. For with an understanding of our proper relations we are better able to perform our allotted part.

Now, in attempting to show the duties of the physician engaged in private practice in his relation to public health, I would not detract in the slightest degree from the importance and nobility of his ministrations to his individual patients. A qualified physician is a boon to any community. He is more: he is a necessity. Said a distinguished professor of the medical college which I was attending, during one of his lectures: "If I had a son who wished to study medicine, I would advise him against it, but, if he insisted, I would tell him to go ahead, not because of the honor there is in the profession; not because of the money there is in the profession; but simply because doctors must be."

* Address delivered at the graduation exercises of the Atlanta School of Medicine, Atlanta, Ga., April 26, 1909.

I was also once much impressed, during a conversation with the late Dr. Gilman, who was then President of the Johns Hopkins University, with his estimate of the character of the practicing physician in the many communities, large and small, which in the interest of education he had been obliged to visit. Although I do not quote him exactly, he said that he always found the representative physician of the community to be also the representative of its best intelligence in matters relating to education, general science, and the important questions of the day.

The physician must do, and generally does, more than to minister personally to the sick and injured. It is not incompatible with his calling to interest himself in other matters; in fact, to do so both broadens and helps him. The old idea that the practicing physician when not visiting his patients should be reading and informing himself from the books of his profession and should think of nothing else is not in conformity with the modern idea. It is well that he should interest himself in some science or subject akin to his own, or some other special study, which will divert his mind and make it fresher to meet the demands of his calling. Such diversion is really a mental rest. True, it should not be carried too far, but with proper limitation it is helpful and beneficial. Thus we see eminent physicians as authors on topics related or unrelated to their profession; as students of law and ordinances, as members of the legislature, as governors, and holders of other high civic offices.

It seems to me that one should resent the idea that a professional calling requires one to be indifferent to what is interesting his family and his neighbors, to the general interests of the community in which he lives, and particularly to his duties as a citizen. The physician, as well as all others, has his civic duties to perform, which should not be neglected.

A most natural sequence of a doctor's practice is an interest in sanitation and hygiene, sanitation having to do with the environment of man, and hygiene with his physical development. While the physician at the bedside is observing the fever or delirium or the racking pain of his patient, as he notes the anxiety and anguish of the family while the little one hovers between life and death, as he bends over the wasting form of the once strong man, and reflects on the financial distress and difficulties of ordinary existence facing those dependent on this man so stricken with disease, what more natural than that he should ask himself, could not this have been prevented? and that his mind should turn to thoughts of sanitation and hygiene? If the case is one of typhoid fever, he will naturally fear lest others of the family may become afflicted with the same communicable disease, due to the same cause; he will think of the dangers of contact and necessity of disinfecting all discharges, of the possible presence of a bacillus-carrier, and begin a mental study embracing the water and milk supplies, drainage and sewerage, soil pollution, and the need of screening against the typhoid-bearing fly, and the adoption of measures to prevent the breeding of flies.

If the case is one of malaria or yellow fever, for the protection of others, he will think of the mosquito and search for and destroy its breeding-places, whether they be stagnant pools or house rubbish such as old tin cans, which on their indented external surface may hold water so small in quantity as to escape ordinary observation, yet sufficient for the breeding of thousands of mosquitoes.

If the case should be one of plague, he would search for insanitary conditions of house and stable favoring the breeding of rats and fleas which are the parasites of rats and which convey the plague from one rat to another and from rat to man. If the disease be uncinariasis, caused by the hookworm, which invades the intestinal tract either through the mouth or the skin of the lower extremities as the victim walks over infected grounds, and is discharged again in multiplied numbers with the alvine secretion, he will think of soil pollution, the chief cause of the prevalence of this disease, and the necessity of sanitary constructions to prevent it.

If the disease be tuberculosis, the great white plague, whose suppression is now engaging the activities of the whole civilized world, his mind will turn to the sanitation of the dwelling; to sufficiency of air space, sunlight and ventilation; to the prevention of flying germ-laden dust, and the disinfection or destruction of sputum.

TUBERCULOSIS AND PREVENTIVE MEDICINE

In view of the great public interest in this one disease, tuberculosis, and the relation which the private physician sustains to it through preventive medicine, it is pertinent to give it here a more than passing notice.

The awakening, both of the medical profession and of the general public, to the importance of this disease, to its fatality and undermining influence on human strength and prosperity, is one of the most notable features of the present century. Its curability and prevention have been demonstrated, and everywhere the popular mind is being aroused, and activities inaugurated and continued for its elimination.

An illustration of this fact may be observed here in Atlanta, where, in addition to other popular and municipal effort, there has recently been displayed a tuberculosis exhibition for the purpose of spreading knowledge and awakening an interest in the general antituberculosis campaign. This particular exhibit is one of a number which have been displayed in the last few months in Florida, Kansas, Nebraska, Missouri and Porto Rico, under the auspices of the National Association for the Study and Prevention of Tuberculosis. Like exhibitions have been held in Maryland, Texas, New York, Pennsylvania and in many other states.

Within the last three months 56 new associations have been organized for the prevention of tuberculosis, making a total of 273 such organizations with which the national association is in correspondence. Of thirty-nine state legislatures in session during the past winter, thirty had under consideration bills relating to tuberculosis, a majority of which gave promise of being enacted into laws.

In September and October last there was held in the city of Washington an International Tuberculosis Congress and exhibition which brought together the leading investigators and workers in this field from four continents. It was the most notable event of its kind in the history of the United States, a great world convention devoted to but one subject—one disease. The stimulating effect of this congress is felt to-day in crowded cities and isolated hamlets.

There has been increasing interest in the prevention and suppression of tuberculosis in this country since 1892, when there was organized in the city of Philadelphia, by Dr. Lawrence F. Flick, the Pennsylvania Society for the Prevention of Tuberculosis, the first or-

ganization of its kind in America. The movement has been actively carried on in a great many countries under philanthropic and governmental auspices.

Its importance from a hygienic and economic standpoint is demonstrable in many ways. Yellow fever, notwithstanding the many panics it has produced, has not caused in the United States, in the past 115 years, as many deaths as occurred last year from tuberculosis in this country. It is estimated that since the year 1793 there have been approximately 100,000 deaths from yellow fever; whereas tuberculosis is estimated to have caused 160,000 deaths last year alone. The mortality from tuberculosis is further emphasized when compared with the epidemic of bubonic plague in India, which has not, for the whole period since its first outbreak in 1896, caused as many deaths in that country in proportion to the population as were caused by tuberculosis in the United States in the same period. Statistics show that tuberculosis in the last four years caused more than three times as many deaths in this country as occurred in action, and from wounds received in action, during the entire period of the Civil War. The figures which sustain this statement are as follows: deaths from tuberculosis in the United States during the last four years, 640,000; deaths in action and from wounds received in action during the four years of the Civil War, 205,070 (federal, 110,070; confederate, 95,000).

I quote from an address delivered by Professor Victor C. Vaughan, of the University of Michigan, before the Tuberculosis Congress in Washington:

Please do not understand from what I have said that I am a pessimist, for such I surely am not, but we must see and appreciate our weakness if we are to relieve ourselves of it, and grow stronger. This crusade against tuberculosis is the greatest work that man has so far attempted. We of this generation are starting it and those who come after us will, we hope, complete it. I certainly believe that the time will come when tuberculosis will no longer curse our race. How soon this time will come it would be folly to predict, for that depends on the intelligence and earnestness of the effort that is put into the work. The eradication of this disease is by no means solely the medical man's problem; it demands the combined intelligence and labor of all men who are interested in the welfare of the race, and the individual who regards it with indifference should find no place in our legislative halls, either national or state. To take the life of a fellow man wilfully or maliciously is murder, the greatest of all crimes; to do so through ignorance or carelessness is manslaughter. In effect it is the same as murder, although in guilt it may be less heinous. The great majority of deaths from tuberculosis are due to manslaughter, and this fact should be recognized. The man who carelessly or ignorantly expectorates infected sputum, which, after drying, may be inhaled and may infect another, is guilty of manslaughter. The same is true of the dairyman who sells infected milk, or of the owner who lets an infected house. It is essential that we recognize these truths before we can be successful in our crusade against tuberculosis. The man who would put arsenic in milk or drinking-water would be regarded by the law as either a criminal or a lunatic, and in either case he would be so dealt with that he could not repeat the offense. The man who sells milk or other food infected with the tubercle bacillus or other disease-producing germs is distributing a more deadly poison than arsenic, and he should be forbidden the continuance of such a practice. We need wise laws in order to restrict and eradicate tuberculosis, and their adoption and enforcement are sure to come as soon as the mass of the people see the matter in the true light.

Our state governments should place tuberculosis on the list of diseases dangerous to the public health, require that all cases be reported, and the local health authorities should see that the disease is not disseminated. I do not think that any

medical man holds that the homes of the tuberculous should be placarded or quarantined, but the tuberculous individual should be minutely and carefully instructed as to the care that he must take with his excretions in order that he may not transmit the disease to others.

The foregoing words of Dr. Vaughan are strikingly impressive.

TUBERCULOSIS AMONG GOVERNMENT EMPLOYÉS

The government of the United States has taken some action with regard to this matter as it relates to its own employés. In an executive order of Feb. 28, 1906, President Roosevelt declared that the non-observance of certain rules by departmental employés should, in the discretion of the head of the department, be considered a just cause for separation from the service. These rules are as follows:

1. All persons in government employ are positively forbidden to spit on the floors.
2. Such persons (employés with tuberculosis) will not be permitted to use the public spittoons, but must provide themselves with individual sputum receivers, preferably of easily destructible material, and carry these with them on arrival and departure. They will be held strictly responsible for the disposal and destruction of their own sputum, so that no other person's health may be endangered therefrom.
3. Such persons must provide their own drinking-glasses, soap and towels, and shall not use those provided for the general use.

TUBERCULOSIS AMONG IMMIGRANTS

Among the millions of immigrants who come to our shores, naturally there are many afflicted with tuberculosis. If allowed to enter the country and mingle with others in tenements and congested districts of our cities, these individuals would be a source of danger and would add many new foci for the spread of the disease. For this reason, all aliens suffering with the communicable forms of tuberculosis are refused permission to land. This applies to those having pulmonary, gastrointestinal or genitourinary tuberculosis. To guarantee against doing an injustice to any one, these cases must be diagnosed microscopically; that is, tubercle bacilli must be found in stained specimens made from the sputa or excretions of the alien. In cases presenting marked clinical signs, but in which the tubercle bacilli can not be found, the alien may still be debarred on the ground that he is suffering from a condition which may interfere with his earning a living and cause him to become a public charge. The medical examination of all immigrants is performed by officers of the Public Health and Marine-Hospital Service.

TUBERCULOSIS AMONG SEAMEN

With regard to seamen of the merchant marine, it is well known that the accommodations furnished sailors on merchant vessels are necessarily cramped and crowded, and in most instances poorly ventilated. When a member of a crew contracts pulmonary tuberculosis, he becomes a serious menace to others who occupy the same fore-castle, unless unusual precautions are taken. Sailors are prone to ship on one vessel after another, remaining but a short time on any one. A consumptive sailor in this way may infect many fore-castles and endanger the health of the sailors who occupy them.

To remedy this condition as much as possible, the medical officers of the Public Health and Marine-Hospital Service were instructed some years ago that whenever a consumptive sailor applied for treatment at a

marine hospital or dispensary the master or agent of the vessel in which the seaman last sailed should be notified, and whenever possible the forecabin or other apartment previously occupied by the seaman should be disinfected. This was done for the protection of other members of the crew.

Deep-water sailors, because of the nature of their lives, are prone not to form family ties. When these men contract a serious chronic disease, like pulmonary tuberculosis, they are apt to suffer in many cases for want of a home, and, in addition, are a greater danger to the community because of not having a fixed domicile. The government has obviated all this by taking on itself the medical care of its sailors and by establishing at Fort Stanton, New Mexico, a large sanatorium for consumptive seamen. At the present time there are nearly 300 consumptive sailors at this institution.

The sanatorium is located on a reservation covering thirty-eight square miles on a plateau in central New Mexico, at an altitude of 6,150 feet. Here many patients recover, and, of course, some die, as no distinction is made, in admission, as to the stage of the disease. The majority of the patients, however, improve to such an extent that the disease is arrested, and the seamen are able to take up some kind of work and become self-supporting, after, however, having been educated in the way they must live to remain well, and not to be a source of danger to others.

NEED OF INSTRUCTION OF THE TUBERCULOUS

A few years ago, desiring a brief rest without going too far from Washington, I went to the Great Falls of the Potomac—about twenty miles from Washington—and registered at the modest hotel on the Maryland side. Everything seemed to minister to my recreation—some fishing, but more particularly the scenery and interesting surroundings; the intake of the water supply of Washington; the rushing falls and huge boulders in the stream; the neighboring woods and the old canal with its locks and dams; the country store and the old-fashioned hostelry with its clean rooms and beds; the rough canal men and the country people—gave interest to my visit, which seemed to have no drawback to its pleasure, until, on the second day, I interviewed a man whom I had seen lounging around the premises, with the air of an invalid and a cough. I talked with him and found he had consumption, that he had come to this spot for recuperation, but that his home was not far away in one of the adjoining counties.

His country doctor had informed him of the nature of his disease, but on inquiring I found that no word of warning had been given him regarding the danger he might be to others; no advice or instructions relating to the disposition of his sputum, which, therefore—without thought or knowledge of the harm it might do—he had been disposing of recklessly everywhere. Here he was, poor man, unconsciously submitting others, myself included, to the danger of infection with the same disease.

Now, that man should have been instructed; some one should have told him, and should have told him promptly, not in a harsh way that would make him feel that he was necessarily a danger to his own people and to others, but in a sympathetic manner, at the same time explaining how easily the peril of spreading the disease could be avoided.

To this end, provision should be made for placing in the hands of every such person a small leaflet or even a

card, explaining what the patient himself should do to prevent his conveying the disease to others—a disaster which he, himself, as well as those with whom he comes in contact, would naturally wish to avoid. Every doctor should have in his possession cards or leaflets of this character, whether they are provided by the state or municipal health authorities, by voluntary health organizations, or by the physician himself.

It is important that individual responsibility regarding this disease be emphasized. Every one should spread the knowledge of it, and persist until a public sentiment is established which will require of every one to contribute to the movement to wipe the disease out of existence. The simple but important rules should become a part of the common knowledge of the community, and their observance as much a habit as any other recognized rule or order of society.

The same feeling of respect and the same observance should prevail with regard to hygienic rules affecting this and other infectious diseases as now prevail regarding the well-known civic ordinances established for the protection of the community.

The same interest, the same patriotism, should be manifested as is shown by citizens in exercising the right of suffrage. The exercise of this right is simply an expression of a desire to take part in promoting the well-being of the community. How highly it is regarded is demonstrated, in both municipal and national elections, by the jealous care with which all our citizens, both of high and low degree, guard this, their sacred personal right. It is the essence of self-government, which in itself is the pride and glory of the present age and is illustrated nowhere and in no degree so vividly as by the great republic of the United States of America. This popular sentiment, this strenuous determination, to have an individual hand in the political welfare of the country, may well be extended, and naturally can be made to extend itself to the preservation of public health. Each individual must feel that it is his right to be protected from this aggressive disease—tuberculosis—and should be persistent in claiming this right.

SPHERE OF NATIONAL, STATE AND LOCAL PUBLIC HEALTH WORK

In the foregoing pages I have endeavored to show that the physician engaged in private practice must meet and know the principles and practice of sanitation and hygiene, the science of public health, and I now desire to show that his interest must be extended still further in this direction, and that he must of necessity acquire some knowledge of the laws and organizations in accordance with which the public health system is administered.

There are three divisions in the public health system of the United States, national, state and municipal, each having its own sphere, yet intimately related with the others. The states leave certain functions to the cities, exercising certain advisory and mandatory surveillance over them, and the nation bears an attitude similar in many respects toward the states.

In the matter of public health the question often arises how much shall be left to the states, how much shall be imposed on the general government? And here arises the old question as to police powers of the states and the restrictions imposed on the national government by the Constitution. There is evidently a growing sentiment that the national government should do far more than it is now doing toward the protec-

tion of the public health, and there is likewise a strong feeling that too much is expected of the national government, and that there is a tendency on the part of the state governments to allow, or to call on, the federal government for service which properly is imposed on the states themselves; and a willingness to surrender even states' rights for the sake of financial assistance. There is danger of an extreme view in each case, and it appears to me that as regards public health the limitations of the Constitution are the very limitations that the best policy would dictate. I do not admit that the limitations of the Constitution are as narrow as is claimed by some strict constructionists. Much may be done under the Constitution that at first blush seems impossible, but which under intelligent interpretation is possible.

On the other hand, measures evidently beyond the powers granted by the Constitution to the federal government would be unwise measures, weakening, as they would, the independence and self-reliance of states and municipalities, and cultivating a weak leaning on the national government, which would lead to a weakening of our national character.

As expressing one view of a proper division of public health work between the national and state governments, I quote from an editorial writer:

The sanitary condition of cities and towns and the control of the influences which affect the health of the people are matters that come very distinctly within the police powers of the states. Regulations and restrictions for the protection of the public health can be best established and administered by state and local authorities, and the nearer their administration comes to the people affected the better. The subject may be neglected in some states, or they may be slow in appreciating its importance and providing for the sanitary well-being of their people, but that fact does not impair their authority or transfer it elsewhere. They may be dilatory or negligent in many things that the national government can not look after for them.

When it comes to dealing with contagious diseases brought from other countries the matter takes a different aspect. The enforcement of measures for preventing their introduction at our seaports, or over our borders, necessarily involves interference with foreign commerce. Vessels have to be detained, inspected and disinfected and passengers and merchandise have to be subject to regulations that concern the people and the interests of the country regardless of state lines. National jurisdiction has here an appropriate field, and is alone adequate to its requirements. Quarantine regulations affecting communication with foreign countries should be national and national only. The same principles may apply in some degree to protection against the transmission of infectious diseases from one state to another through the agencies employed in interstate traffic, as interference with those agencies pertains to the regulation of commerce between the several states.

In addition to the functions of the national government as outlined in the foregoing quotation, the government is engaging in many important operations quite within its proper sphere. Among these may be mentioned the enforcement of the law and regulations regarding the manufacture of vaccine, toxins and anti-toxins; the law relating to pure food; it is engaged in scientific investigations of the cause of disease and other matters relating to public health; it publishes vital statistics, and disseminates information regarding health conditions in this and other countries; it publishes scientific bulletins on health matters, and its Public Health Service is by law brought into cooperation with the health boards of the several states.

The state boards of health are yearly increasing in power and efficiency, and no scheme of sanitary organization in the United States could be successful which should not include the state health organizations.

GROWTH OF THE PUBLIC HEALTH AND MARINE-HOSPITAL SERVICE

The Public Health Service of the United States, under the Treasury Department, was established by act of Congress, by enlargement and change of name of the Marine-Hospital Service in 1902. It may be of interest to sketch briefly the origin and growth of this service. Beginning with 1789, Congress established marine hospitals at various ports of the country to encourage the merchant marine, and physicians were appointed by the respective collectors of customs, in charge of these hospitals. In 1873 the service was reorganized, the physicians made into a corps appointed by the Secretary of the Treasury after examination, with a supervising surgeon-general in Washington, appointed by the President. In 1889 the corps was placed on a still better basis, requiring appointment by the President and confirmation by the Senate. The care of sick and disabled sailors in hospital led to supervision of their sanitary welfare aboard ship, and as sailors and their ships are the usual carriers of infection from foreign ports to our shores, when the first national quarantine law in 1878 was passed, the responsibility for its enforcement was naturally placed, in the same law, on the Marine-Hospital Service. Assisting the states in the exclusion of epidemic disease under the first quarantine law, the service was naturally called on to aid in the suppression of epidemic disease which escaped the barriers, and in the performance of this duty the marine-hospital officers became experienced in enforcing sanitary measures and in the principles of sanitation. In the meantime, a laboratory was established for the scientific investigation of the diseases treated in the hospitals, which was extended subsequently to all contagious and infectious diseases and matters relating to the public health, and from this first laboratory has been developed by succeeding laws the present Hygienic Laboratory of the Public Health and Marine-Hospital Service.

For years the Marine-Hospital Service was engaged, under various acts of Congress, in the performance of public health duties quite apart from its original function, until finally these duties became so great and numerous and the care of sailors in hospitals relatively so small a matter, that Congress in 1902 changed the name to the Public Health and Marine-Hospital Service, and enlarged its scope in public health work. Today it has a corps of nearly 450 medical officers, 50 pharmacists and a total personnel of about 1,740. It treats annually about 58,000 sick and disabled seamen in its 22 marine hospitals and 120 other relief stations. It conducts the maritime quarantine of the Philippine Islands, Hawaii, Porto Rico and the United States. It has its officers in the ports of China, Japan, India, Europe, Central and South America, and the West Indies, to sign the bills of health of vessels, examine immigrants, and give general sanitary information. It inspects all arriving aliens, to enforce the immigration health laws, maintains a sanatorium for consumptives in New Mexico, a well-established institution for the investigation of leprosy in Hawaii; maintains the Hygienic Laboratory at Washington, with a personnel of sixty workers, for the investigation of disease and matters relating to the public health; and a Public Health

Bureau at Washington, with six divisions, through which the operations of the service, properly classified, are conducted by trained medical officers under the direction of the Surgeon-General.

RESPONSIBILITY OF THE PRIVATE PHYSICIAN

In the public health system of the United States, combining the national, state and local forces, the physician in private practice is an important factor. Indeed, he is the first unit, in that on him devolves a duty of reporting the facts that naturally first come under his observation. He has a direct responsibility to the state, in giving the notifications and making the reports required. He is the first to see and know the conditions and diseases which, at first local, may become afterward state or national in their importance. He should loyally support his state and local board of health.

In conclusion, I would say to the members of the graduating class: Do not be dismayed by the obligations, additional to those of your practice, which have just been indicated. At the beginning of a professional career, I know that the field of study, investigation and labor, opened up to the practitioner through the usual curriculum of a medical college, seems so large, so difficult to cover, that one is apt to be apprehensive as to acquiring all the information necessary in the several branches of medicine, and keeping apace with developments, and state medicine may seem an additional responsibility. But you have the advantage of youth and strength. Many years are before you. Your capacity and knowledge will grow with the increasing years. You surely will be able to master these principles of hygiene and sanitation, to become familiar with the public health laws and regulations, and to aid in their enforcement, thus adding to the dignity of your profession and the value of your lives to the common wealth; and will worthily fill the important place allotted to you in the resistless march of human progress.

CHRONIC CHOLECYSTITIS AS A CAUSE OF MYOCARDIAL INCOMPETENCE

REPORT OF THIRTEEN CASES

ROBERT H. BABCOCK, M.D.

CHICAGO

It is said that one out of every ten adults has disease of the gall bladder and that one out of every thirteen has gallstones. If these figures are only approximately correct, there is certainly a remarkable discrepancy between the frequency of the occurrence and of the clinical recognition of chronic cholecystitis. This discrepancy is due partly to the ignorance of general practitioners concerning its frequency and partly to the obscurity of its symptoms. Yet when one's attention has been once directed to the subject, one is able to recognize certain symptoms which are very suggestive if not actually convincing.

Prominent among these is indigestion or stomach trouble, with or without more or less epigastric distress, distention or uneasiness coming on several hours after a meal and accompanied or relieved by eructations of gas. Not uncommonly these symptoms of indigestion occur at night, often waking the individual from

sleep toward morning, and they are sometimes associated with palpitation or irregular action of the heart. It is not uncommon for this discomfort in the stomach to be relieved by the taking of soda, food or even a drink of plain water. As belching of gas is apt to follow the ingestion of these substances, the relief experienced is generally attributed to the removal of gas from the stomach. The gas is tasteless and odorless as a rule.

Pain is not an essential symptom even when gallstones exist; and when the chronic cholecystitis is unattended with calculi there may be no history of pain whatever and even no tenderness except during and directly after an acute exacerbation of the gall-bladder infection. In some instances slight colicky pains are felt, and in two of my cases complaint was made of dull, intermittent pain below the heart. Attacks of "congestion of the liver" may be admitted, and at such times there is likely to be vague pain or tenderness in the region of the liver. In some cases also there is pain in the right shoulder, considered rheumatic, or in the back near the inferior angle of the right scapula, and Ewald's area of cutaneous hyperesthesia in the right back low down is generally discoverable.

There is, however, another point of interest in this matter of the symptomatology of gall-bladder disease; namely, the occurrence of disorders in the action of the heart, from arrhythmia and precordial oppression without dyspnea to demonstrable dilatation and incompetence dating usually from some attack of biliary colic or acute cholecystitis and thenceforth maintained by recurrences of the acute disturbance. This is shown by the case reports here narrated, the individuals having sought medical aid because of heart trouble, and, with but two exceptions, having no suspicion of anything being wrong with the gall bladder. Excepting in two cases in which outspoken attacks of hepatic colic were experienced, the symptoms referable to the heart overshadowed those pertaining to the gall bladder, and this viscus became an object of suspicion either on account of the complaint of "indigestion" or of facts in the anamnesis which directed attention to the gall bladder.

Without exception also in each of the cases reported, palpation detected a swelling in the proper location of the gall bladder which in most instances was shown by operation to be a Riedel's lobe. In nearly all cases, repeated and careful palpation was required before the swelling could be detected with certainty, and this was possible only after a more than usually pronounced attack of pain or indigestion. It was possible also at such times to perceive slight rigidity of the right rectus. The patient's color also was generally muddy or subicteric. There was not always a history of typhoid fever, while two patients gave a history of illness supposed to have been malaria, and some declared they never had been ill.

The cases to be reported number thirteen and have been divided into four groups in accordance with their clinical, not their pathologic, features. 1. In this group are five cases of pronounced cardiac incompetence showing considerable dilatation with arrhythmia and feebleness of heart's action with murmurs; in short, subjective and objective symptoms of serious heart disease. 2. This group comprises two cases in which there were attacks of pain that had been called angina pectoris or were of an anginoid character, and which attacks were followed by evidences of myocardial inadequacy. In

this group is included also one other case in which there was dull infracardiac pain, together with arrhythmia of the pulse and a moderate degree of dyspnea on exertion, both dependent on recognizable though not great dilatation of the heart. 3. In this group are embraced three cases of intermittence of the pulse of long standing and very intractable, but without dyspnea or other marked subjective symptoms of myocardial inadequacy. Two patients were much benefited by operation and thereafter enjoyed greater freedom from intermittence than by any previous lines of treatment. 4. This group includes two cases of valvular disease in which cardiac competence was destroyed either by outspoken attacks of hepatic colic or distressing symptoms thought referable to the stomach at first, but subsequently attributed to the gall bladder because of the recognition of a Riedel's lobe. A number of other cases could be reported, but are omitted because either not subjected to operation or not so plainly showing the signs of gall-bladder disease as to make its diagnosis certain.

CASE REPORTS

GROUP 1.

CASE 1.—Patient.—G. R., life insurance agent, aged 44, examined Nov. 12, 1903, on account of heart trouble, had suffered from a biliary colic two years before and been jaundiced for ten days. In March, 1903, he had experienced a second attack of colic and been jaundiced for three weeks but had not been operated on because of the state of his heart. All other illnesses were denied and habits had been good. The chief symptoms were dyspnea of effort and distress in the region of the liver.

Examination.—The only points of the physical examination worthy of note were the following: Icterus absent, temperature normal and urinalysis negative; accessible arteries not thickened, pulse intermittent and so arrhythmic that its rate was not recorded; the feeble apex beat in fifth interspace below left nipple and deep seated dullness increased transversely from one inch to right of sternum to four and a fourth inches to left of the midsternal line; no murmurs, but all sounds very feeble and the second succeeding the first by too short an interval; below the right costal margin a tender, palpable swelling that extended downward the width of two fingers, while elsewhere the liver could not be felt. The diagnosis was made of cardiac hypertrophy and dilatation with inadequacy, due to the cholecystitis and hepatic colic, not to chronic myocarditis. Accordingly an operation was advised in the belief that it would not prove especially dangerous, if properly performed, and would remove the source of irritation which was preventing the restoration of cardiac competence.

Later History.—The subsequent history is interesting. After a period of much suffering from both heart and gall bladder the man at length went to Rochester, Minn., in the hope of an operation, but this being denied on account of the state of the heart I saw him again at St. Luke's Hospital in a very serious state of myocardial inadequacy, somewhat icteric and his gall bladder swelling, very tender and large. An operation was again urged but declined because of the apprehension occasioned by the unfavorable opinion previously received. In February, 1905, a letter received from him stated that, although his heart still troubled him, he was able to attend to business; and quite recently this man, now 50, was married for a second time and was reported actively pursuing his vocation, although still troubled at times by both heart and gall stones. Consequently it is believed that had his gall bladder been opened and drained when this was first advised he would have endured the operation, his heart been reinstated and years of suffering prevented.

CASE 2.—Patient.—T. C. H., policeman, aged 43, examined in June, 1904, on account of heart disease, gave the history of illness of ten months duration. Syphilis was denied and whiskey used to excess only during present illness. Two years previously patient suffered from chills and fever which, occur-

ring again ten months previous to examination, was called malaria. The perspiration was of bad odor and there was heaviness in the pit of the stomach. Ten days later palpitation and dyspnea set in and six months before the patient was seen his feet began to swell; he went to Mudlavia, where he took but fourteen baths. He was then obliged to return home and take to bed; he changed from doctor to doctor without relief. In April the abdomen was tapped and fluid withdrawn.

Examination.—Present symptoms were dyspnea on slight exertion, cough, and scanty muddy-looking sputum, anorexia and vomiting, poor sleep on account of shortness of breath. The skin was slightly jaundiced and pitted on pressure over lower extremities to knees, pulse 84, irregular and of low tension, radial arteries slightly thickened, tongue moist and red, temperature 99.9 F., leucocytes 12,600, urine slightly albuminous, lungs negative, but heart dilated, as shown by absence of impulse and increase transversely of both absolute and relative dullness, which latter reached from $1\frac{1}{4}$ inch to right of sternum to 1 inch outside of left nipple, all heart sounds very feeble and the first at apex impure. The liver was palpable and in the right parasternal line below the costal margin could be felt a swelling of the size of a small fist tender to palpation and the right rectus muscle was tense.

Diagnosis.—The history indicated that the symptoms of heart disease first appeared about ten days after the onset of an illness supposed to be malaria, but as malaria, in my opinion, does not cause disease of the heart and on account of the findings, namely, an enlarged and tender gall bladder, icterus, slight febrile temperature and moderate leucocytosis, the opinion was expressed that the dilatation and inadequacy of the heart had been initiated by an acute cholecystitis and was maintained by what was probably an empyema of the gall bladder. The heart muscle was thought to have suffered irreparable damage and yet without removal of the disturbing element by opening and drainage of the gall bladder, a restoration of even a part of its old-time power was impossible, although even after an operation a recovery of compensation was questionable. Accordingly operative interference was advised.

Operation.—The recommendation was accepted and his physician at home performed the operation. From him it was learned that the gall bladder was found enlarged, thickened, white and distended with mucus and dark bile but without stones. Local anesthesia was used.

Postoperative History.—The man stood the shock of the operation well and for seven days was progressing finely, when suddenly the flow of bile ceased, his temperature rose, the heart grew still more feeble and death occurred on the eighth day after the operation. No autopsy was permitted, but I believe that the findings at the time of the operation substantiated the diagnosis in so far as the relation between the heart and gall bladder was concerned, although an empyema did not exist.

CASE 3.—Patient.—C. S. H., real estate agent, aged 53, was first examined in November, 1904, because of heart trouble and shortness of breath for the past two weeks. Habits were excellent and venereal diseases denied; he had had malaria twenty-five years previously and in June, 1903, pneumonia, following which severe attacks of abdominal pain, coming on three to four hours after meals and compelling the patient to lie on his right side with knees drawn up, yet without nausea or vomiting. The last attack of pain had been in June, 1904, and had been diagnosed as acute appendicitis by his physician, who had kept him in bed and on a strict diet which had been maintained up to the present time and been responsible for his loss of weight. His complaint was dyspnea of effort and indigestion characterized by formation of great quantities of gas.

Examination.—Marked emaciation and pallor but no icterus; pulse irregular and intermittent, varying from 88 to 104 per minute; arteries soft and veins not turgid; systolic blood pressure (Gaertner), 95 mm.; no edema. Urine showed a trace of albumin and a few granular casts but no sugar or bile. Temperature 98 F. but leucocytes 12,200. Right lung showed reflex retraction at base behind but no rales. Heart dilated, the total transverse diameter being six inches, impulse very feeble and first sound at apex weak with a faint soft murmur, while

at base all tones were feeble, the second pulmonic being somewhat louder than the corresponding aortic. Examination of the liver revealed a swelling that extended from the costal margin in right parasternal line to the level of the umbilicus and was sensitive both to palpation and percussion. The stomach was somewhat dilated.

Diagnosis.—This disorder was plainly serious myocardial inadequacy with dilatation of both ventricles and muscular mitral insufficiency, but the question of moment concerned the state of the heart muscle and the possibility of its restoration to a fair degree of function power. The history of pneumonia eighteen months before and the man's age rendered likely the existence of a chronic myocarditis. But inasmuch as the gall bladder complication appeared responsible for the break-down of cardiac competence and seemed militating against recovery an operation was recommended in the hope that subsequent rest and treatment might restore some degree of compensation.

Operation.—Accordingly the gall bladder was opened a few days later and was found to contain stones besides exhibiting the usual changes of chronic infection. The heart stood the slight shock of the operation and ten days subsequently was reported by the attending physician to be showing a little improvement.

Postoperative History.—Unfortunately this improvement did not last and when the man was examined three months later the dilatation and myocardial inadequacy were still very serious. Nevertheless he persisted in his attempt to do business, with the result that he overstrained his weak heart, was removed to a hospital for treatment, but to no purpose, and death took place in March, 1906.

CASE 4.—Patient.—H. C. S., manufacturer, aged 61, was seen in April, 1907, because of heart disease. Ten years previously he had had symptoms of glycosuria but not of diabetes and at length sugar had disappeared; seven years before the present illness an operation for perirectal abscess was followed by a perineal abscess that broke into the bladder; several years prior to the glycosuria some sort of trauma with internal injury. In November, 1906, he had a fall, succeeded two weeks later by numerous attacks of epigastric pain that eventually became constant, was accompanied by fever and kept patient in bed. In December, while sitting up in bed to take a drink, he was seized with a sudden sensation of something having burst in the abdomen and fell back in a state of shock from which he was aroused with difficulty. From this obscure illness convalescence was slow and never complete, so that when Mr. S. went south in February he had slight ankle edema and symptoms of cardiac incompetence; by end of March ascites, and a physician ordered rest in bed, cathartics and heart tonics; as soon as able to travel the patient returned home and I examined him.

Examination.—Symptoms were dyspnea on exertion, slight cyanosis, pulse regular and 96 to 105 at rest, systolic blood pressure 154 (Janeway), diastolic 80, radials moderately stiff, no fever, and appetite, digestion and bowel movements good, urine increased at night but without albumin. Physical examination, briefly stated, yielded the following: Heart dilated as shown by feeble apex tap $4\frac{1}{2}$ inches to left and transverse increase of both superficial and deep cardiac dulness, the tones feeble and first at apex obscured by systolic murmur of maximum intensity over right ventricle; the second sound at apex doubled and aortic second tone intensified. Lungs were negative. The really interesting feature in this case was connected with the liver, which on superficial examination appeared enlarged from stasis. It was soon discovered, however, that the enlargement was strictly circumscribed and presented the shape of a swelling with convex upper surface and slightly uneven inner border that projected from the costal arch almost to the level of the umbilicus. This swelling was tender to palpation and by means of the tuning-fork could be differentiated from the body of the liver, which percussion showed of normal size and shape. Lastly, there was a right inguinal hernia.

Diagnosis.—Dilatation and incompetence of the heart, probably also some degree of chronic myocarditis, complicated by an intra-abdominal condition, thought to be a cholecystitis. It was stated also that the illness in the preceding fall with in-

termittent and afterward constant epigastric pain had been an acute exacerbation of an old gall bladder infection—that the sensation of something having burst in the abdomen and the resulting shock might have been due to rupture of the distended gall bladder, and that unless this complication were removed surgically restoration of cardiac competence was impossible.

Operation.—Accordingly a surgeon was called in who agreed in the diagnosis of chronic cholecystitis and concurred in the advisability of operative intervention. The consideration of the heart symptoms having developed during or directly subsequent to the acute illness in the fall gave hope that after removal of the abdominal complication myocardial adequacy might be regained. A week later the operation of opening and draining the gall bladder was done under ether. On incision of the abdominal parietes a clear, sticky serum gushed forth which coagulated speedily and the swelling collapsed. The gall bladder was then found, stitched to the abdominal wall, opened and drained. It was large, white, thick and filled with viscid almost black bile and no calculi.

Postoperative History.—A week later the pulse was of normal rate, the murmur gone and dilatation no longer demonstrable. Before long the man was going to his office but with the drain still in his gall bladder, and he had no further cardiac symptoms except for a short time when the flow of bile became checked. The pulse then became rapid but again fell to its wonted rate on re-establishment of the discharge of bile. In August he suffered a fall from a height of eight feet, which accident was followed by a return of the tumor and pain in the abdomen but without disturbance of the heart's action. Consultation with another surgeon resulted in a diagnosis of pancreatic cyst and a decision to operate. This was never completed, however, as death occurred on the table.

Autopsy.—This disclosed no cyst of the pancreas but a remarkable condition of the omentum. This was attached to the hernial sac and so twisted on itself as to have formed a pouch at its upper part. Into this pouch serum had transuded in consequence, probably, of constriction of the mesenteric vessels, and it was this localized ascites that created the swelling in the vicinity of the gall bladder.

CASE 5.—Patient.—J. B., marine engineer, aged 47, was seen in May, 1907, because of dyspnea and other symptoms, due, as he had been told, to heart disease. The only points in the history worthy of note were typhoid fever in youth and, ten years before the present illness, a severe abdominal pain relieved by a purge.

Physical Examination.—The patient's height was 5 feet 7 inches, weight 177 but normal 202 pounds; conjunctivae subicteric; no edema, or fever; urine negative; pulse 107 and regular, radials slightly thickened; systolic blood pressure 112 and diastolic 75 (Janeway). There was no perceptible cardiac impulse and deep-seated dulness was greatly increased to left, reaching six inches to left of the midsternal line; sounds were all weak but clear and no murmur was audible. The chest and abdomen were negative. Questioned particularly as to other symptoms than shortness of breath, the man mentioned occasional pains in the lower chest in front which, beginning on the right side, extended upward and across to the left. The diagnosis seemed clear of cardiac hypertrophy with dilatation in consequence of chronic myocarditis and the patient was ordered to bed in charge of a physician in proximity to the man's temporary abode.

Course of Disease.—Treatment for the next two weeks seemed to be improving the condition of the heart, when suddenly, in June, the patient experienced acute pain in the region of the gall bladder, temperature rose to 103 F. with great acceleration of the pulse, marked tenderness below the right costal arch and rigidity of the rectus. Acute cholecystitis was diagnosed and an operation performed, the surgeon finding an enlarged enormously thickened and white gall bladder distended with sticky, black bile and mucus. But the significant feature of this case is that after the opening and drainage of his gall bladder the area of cardiac dulness became appreciably reduced in size and the man lost all symptoms of myocardial

incompetence. When last heard from a few months ago the man was following his occupation as chief engineer on one of the boats on our Great Lakes.

GROUP 2

CASE 6.—Patient.—Mr. McA., contractor, aged 73, seen in consultation May 16, 1907, because of angina pectoris, heart and kidney disease, gave the following history: He had considered himself well until three weeks ago, when one morning while sitting at his office desk, he was seized with a severe pain in the epigastrium and lower part of the chest. The patient arose, went into his cashier's room adjoining and asked to have a physician summoned. This doctor considered the pain due to indigestion and prescribed accordingly, but the pain did not cease for four hours. Symptoms of cardiac incompetence developed the day following and the family physician quite naturally regarded the attack as having been one of angina pectoris, and finding the heart dilated ordered the patient to bed. The only other illness in the patient's recollection had been thirty years previously and consisted of abdominal distress with fever and diarrhea. The symptoms were shortness of breath, especially at night, troublesome eructations of gas, urine scanty, showing a few fine granular casts but no albumin, temperature normal.

Examination.—The patient was in bed, breathing somewhat hurriedly and superficially, looked pale and thin; no edema; pulse 76 to 80 and frequently intermittent; systolic blood pressure 140 (Janeway) and diastolic 78, radials slightly thickened, veins negative. The heart-apex beat was distinct but feeble in sixth space five inches to left of the midsternum and relative dullness increased to one inch outside nipple; the first sound at apex accompanied by blowing systolic murmur and at base both second tones accented. The lungs were negative. The abdomen was thin, and below the right costal margin could be felt what seemed to be the liver. Careful percussion, however, showed the liver to correspond with the inferior costal arch, while below this line was a smooth, rounded body which, slightly tender, glided easily beneath the fingers with each act of respiration and by means of the tuning-fork could be differentiated from the liver. May 19 the patient had another slighter attack of pain in the hepatic region, and at my visit on the 22d the conjunctivæ were subicteric, the temperature was about 100 F., pulse more frequent and more irregular, heart's dullness still more increased, the murmur more intense, the liver congested and the swelling at its lower edge more easily palpable and unmistakably tender.

Diagnosis.—This was now clear and the opinion unequivocally expressed that the underlying cause of the trouble was chronic cholecystitis which had led to an attack of hepatic colic and not angina pectoris and had precipitated the myocardial break down. Degenerative changes in heart, arteries and kidneys were present no doubt, and on this account the gall bladder complication was preventing and would prevent restoration of compensation unless the gall bladder were removed by operation. This being hazardous, surgical counsel was obtained from three men of wide experience. The first was noncommittal; the second dismissed the case as purely medical; while the third coincided in the diagnosis already given and the view that although attended with great risk an operation afforded the only chance of the heart being restored to even a fair degree of competence.

Operation.—The friends decided to incur the risk and on May 25 the gall bladder was opened under gas. This anæsthetic was borne badly, but at the end of eighteen minutes was withdrawn, as the operation was almost finished. Such was the rigidity of the abdominal wall, however, that a little more gas was ordered, whereupon respiration ceased promptly and death took place in spite of vigorous efforts to revive the patient. As in the other case, the gall bladder was large, thick, white and filled with black, viscid bile. No calculi were obtained. The only consolation possible under the circumstances was the corroboration of the accuracy of the diagnosis regarding the part played by the cholecystitis in destroying the competence of a heart muscle already diseased and only requiring a biliary colic to overpower its potential integrity.

CASE 7.—Patient.—Mrs. H., housewife, aged 64, was seen in consultation May 22, 1907, because of great irregularity of the pulse and other symptoms of heart disease. She had had typhoid fever in childhood; twenty-five years before, when pregnant, she had been trampled on in a crowd, and this was followed by bloody vomiting but not abortion; seven years before the present illness a severe epigastric pain lasting two or three days and slighter pains at intervals ever since; during the past winter an almost steady distress in region of stomach and for past three weeks shortness of breath on exertion. The present illness began with severe epigastric pain, which, radiating into the chest, was thought to be angina pectoris, especially as the patient had signs of mitral stenosis.

Physical Examination.—The patient was in bed, with rapid, feeble but regular pulse, rectal temperature of 101 F., a moderately distended, tympanic abdomen with marked tenderness and appreciable rigidity directly below the right costal margin. The heart showed a tapping apex beat, increased dullness, both absolute and relative, a short presystolic thrill and murmur ending in a faint systolic whiff heard with the thumping first tone. The diagnosis was made of acute infection of the gall bladder with gallstones, the pain having been a hepatic colic, not angina, and this state of things having broken down the compensation of a mitral stenosis of moderate degree.

Operation.—As there was danger of acute peritonitis as well as of irreparable injury to the heart an immediate operation was advised. This was consented to with reluctance and hence delayed until the following morning. Beginning peritonitis was discovered and, in addition, a large, thick gall bladder which contained pus and a single black stone.

Death occurred thirty-six hours subsequently.

CASE 8.—Patient.—J. A., hotel keeper, aged 48, sought advice of me Dec. 1, 1908, because of dyspnea, irregularity of the pulse and a dull infracardiac pain present most of the time. The history, obtained with much difficulty, was in brief as follows: Typhoid at 14 years of age; fifteen years ago congestion of the liver; six years ago, after a bicycle ride, severe pain in epigastrium with vomiting, lasting six hours and called gastritis; since that time frequent bilious attacks; in May, 1908, pain in the left thigh with nausea and a few hours later, while walking, pain in the left leg with limping, and later, while sitting still, a slight stroke which speedily disappeared, leaving no ill effects behind; a week subsequently pain in region of liver and jaundiced; previous to his experience in May the patient was in the habit of taking an early morning plunge from the wharf into the ice-cold river without any ill effect on his heart; since May had not been well.

Physical Examination.—Patient subicteric but well nourished; pulse 116 in dorsal decubitus and so arrhythmic that the rate could be determined only by auscultation of the heart; systolic blood pressure 155 (Erlanger), accessible arteries slightly thickened; temperature and urine negative. Heart dilated, apex beat in fifth and sixth interspaces five inches from the median line and deep dullness much increased transversely, from 1½ inches to right of midsternum to 5¾ to left; many extrasystoles and over the body of the heart a feeble blowing systolic murmur, the pulmonic second tone accentuated. Abdomen corpulent, but below the ribs in the right parasternal line a body feeling like the liver extended downward in a convex shape for about two inches and from the right mammary to the median line, but not especially tender to palpation. The diagnosis was made of dilatation of the heart with incompetence, probably a chronic myocarditis, the incompetence having resulted from an attack of the hepatic colic in May, cholecystitis having caused also an intermittent claudication.

Course of Disease.—This man subsequently returned to Chicago and received treatment by means of rest in bed, cardiac tonics and Nauheim baths. The heart became reduced in size and the murmur disappeared, while the tones grew stronger, but the dull infracardiac pain persisted, and from time to time, especially when this pain was most persistent, the Riedel's lobe could be made out with great ease. In February the gall bladder was opened under ether and drained. It was much thickened, enlarged, white and filled with mucus, dark-colored bile and sand. When the man went home ten days later his pain had disappeared entirely and his heart's action was slightly

less irregular. He felt perfectly well. A recent report states that when the drainage-tube was removed after six weeks and the wound closed, great abdominal distention and distress, weakness of heart and asthma occurred, necessitating reopening of the wound, on which mucus and bile escaped with great relief to symptoms. What the ultimate effect on his heart will be can not be predicted, but it is feared that the heart muscle has suffered irreparable damage.

In this case, as well as in one other of which I have notes, the pain felt below the heart was spoken of as in the heart. In this connection mention may be made of the circumstance that in a certain instance when a surgeon was exploring the gall ducts for stone the patient exclaimed, "Oh, that gives me a pain in my heart!" I also recall a case seen in consultation with Dr. McCaskey of Fort Wayne, in which besides myocardial inadequacy there were attacks of pain that bore a close resemblance to angina pectoris, yet may have been hepatic colic, since there was a history, together with local findings, that seemed to implicate the gall bladder. It is these considerations that have led to the classification of some of the cases reported in Group 2; namely, that in which there is pain simulating angina pectoris.

GROUP 3

CASE 9.—Mrs. B., aged 57, short and stout, consulted me in April, 1907, on account of a heart difficulty from which she had suffered for three years. She had a fever in the spring of 1904 on arriving in Italy from India, which illness was called malaria. Directly thereafter her heart began to trouble her and she was sent to Bad-Nauheim, where she took a course of baths under Dr. Schott. This course of treatments was repeated in the summer of 1905, and although improved thereby she still suffered from the same symptoms. No other facts of importance could be ascertained. Symptoms: persistent and annoying, irregularity of the heart, with a feeling of weakness and oppression in the region of the heart. This irregularity of the heart was especially bad when she was having indigestion, and at such times she had bad nights and was much exhausted. Naturally ambitious and energetic, she now could endure very little.

Examination.—The pulse was frequently intermittent, 80 standing and 70 in dorsal decubitus, systolic blood pressure 112 (Janeway). Percussion and palpation of the heart were impossible because of the mammary development, but the tones were feeble, especially the first, which in all areas was scarcely audible. The liver could not be palpated, but below the costal margin, right parasternal line, there was tenderness. The two points that attracted particular attention were the absence of dyspnea and the history of the cardiac symptoms having originated in or directly after an attack of supposed malaria. The want of dyspnea and the fall in pulse rate from the standing to the recumbent posture seemed to cast doubt on there being any serious degree of myocardial weakness, while the tenderness below the ribs and the belief that malaria does not cause heart disease directed attention to the possibility of the illness in 1904 having been an acute cholecystitis.

Course of Disease.—During the next six weeks Mrs. B. took a course of Nauheim baths and digitalis with slight improvement subjectively but no appreciable change in the pulse or heart sounds. At length in June she reported her heart as particularly bad because of an unusually bad night from indigestion. The pulse was more intermittent than had ever been noticed, but the point of special interest was connected with the gall bladder. Palpation of the liver had been made repeatedly but always with rather undecisive results. This day, on the contrary, it required but a moment to enable me to feel a smoothly rounded body projecting downward from the inferior costal margin about two inches, which was tender and glided easily down against the fingers with each act of quiet inspiration. The patient was now told that she had chronic cholecystitis, probably a sequel to an acute infection of the gall bladder three years before and that the irregularity of the heart was secondary to or greatly intensified by the chronic infection of the gall bladder. An operation was advised.

Operation.—On June 16 the viscus was opened and drained under ether. There was the usual finding of a large, thick, white gall bladder filled with tarry bile but, in addition, a quantity of sand and small stones.

Postoperative History.—Recovery was uninterrupted, but a little digitalis was ordered for a short time both during the days directly following and for a week or so in July. Not only did the patient improve in every other respect but the pulse soon became regular, and with occasional exceptions has remained so. During December, 1908, and until February, 1909, two months, the heart's action remained perfectly regular, but the patient then contracted an attack of grip, and at present writing, April 4, her pulse intermits but nothing like so frequently as it used to. Another noteworthy fact is that soon after the operation the heart tones became appreciably clearer and stronger and in particular the first sound previously almost inaudible became distinct. The patient herself is more than pleased with the result of the operation.

CASE 10.—*Patient.*—W. M. M., dealer in live stock, aged 58, was seen on July 8, 1908, on account of attacks of palpitation with eructations of gas which awoke him in the small hours of the night, and for which he had been treated without benefit for six months. He denied dyspnea and all other symptoms except flatulence and also declared he had never been ill before.

Physical Examination.—This showed a healthy-looking man of medium height and 158 pounds in weight. The pulse was of variable rate in consequence of frequent irregularity and intermissions, but when regular for a few seconds and running at the rate of 78. Systolic blood pressure was 148 and the brachial arteries felt rather stiff. Temperature and urine were negative. Heart: The indistinct apex beat was in fifth space below the nipple and relative dullness was increased to the left to $4\frac{3}{4}$ inches from the median line. The first tone at the apex was somewhat valvular and over the body of the heart was accompanied by a feeble systolic murmur heard with especial distinctness during each strong beat following a feeble systole. These extrasystoles were at times frequent. The abdomen was negative excepting that below the ribs on the right could be felt indistinctly a resisting body seeming very like Riedel's lobe. There was no tenderness.

Course of Disease.—Treatment by means of digitalis, strophanthus, etc., and various remedies to improve digestion, including correction of the diet, was absolutely without effect on the heart. At length in August, after an unusually troublesome time with his heart, palpation revealed the Riedel's lobe or gall bladder, whichever it was, so plainly that the opinion was expressed that a chronic cholecystitis was responsible for the indigestion and behavior of the heart, and an operation was advised. This was done under ether on August 28, and a thick, white, large gall bladder filled with molasses-like bile but no stones, was opened and drained. Convalescence was uninterrupted, but for a while strophanthus was administered as the state of the heart muscle was doubtful and it was desirable to reduce what slight dilatation was present. At length the heart, previously intractable to all treatment, became regular and for several months gave the man no trouble whatever. Recently, however, this patient has returned, complaining again of his annoying heart symptoms. This time flatulence was particularly pronounced and intestinal toxemia was thought to be the cause of the disturbed heart action. At the present writing treatment addressed to this condition is steadily improving the rhythm of the pulse.

GROUP 4

CASE 11.—*Patient.*—Mr. A., bank cashier, aged 39, consulted me in October, 1908, because of irregularity of the heart's action, slight dyspnea on stairs and fatigue out of proportion to its cause. He thought these symptoms had existed since a certain occasion when he overstrained himself in swimming two years ago. In the winter of 1907 he had been threatened with typhoid fever and since then had been much troubled with gas on the stomach. Other illnesses were unimportant and habits were good.

Physical Examination.—A healthy-looking man; pulse 96 and very arrhythmic, systolic blood pressure 131 and diastolic

80, vessels negative. Temperature, skin, tongue and urine were negative. Heart: Apex beat indistinct in fifth space five inches to left of midsternum; deep dulness reached 5½ inches to left and also slightly increased to right. The sounds were short and valvular and the first at apex was accompanied by a faint whiff most audible with the systole immediately succeeding an intermission. The abdomen was negative.

Course of Disease.—As the heart was dilated and serious incompetence seemed imminent, Mr. A. was advised to take a course of Nauheim baths, which he did with much benefit, his heart's area becoming reduced in size and the murmur disappearing with appreciable improvement in the strength of the tones. His indigestion was troublesome, however, and on one occasion he was given four quarter-grain tablets of calomel with soda to take that evening at half hour intervals. The next day he returned with a still more intermittent pulse, saying that half an hour following the first tablet and directly after the second he had been seized with cramps, vomiting and diarrhea which lasted well into the night and that slight colicky pains were still present. In the belief that these symptoms were not due to the calomel but to a possible gall-bladder trouble, careful palpation of the liver was made with the discovery of a small, tender swelling in the exact location of the gall bladder and extending about two inches below the costal arch. Two days later this swelling was less tender and less easily felt. By the end of the week all sensitiveness had subsided and the mass could be detected with difficulty. The precise degree of influence exerted on the heart by the cholecystitis, and whether or not it was responsible for the maintenance of the arrhythmia was a question hard to decide in view of the history of possible strain while swimming two years before. Nevertheless, an operation was recommended but was not performed owing to an adverse opinion given the patient in Rochester, Minn. This patient has since reported himself as pretty well, having but slight annoyance with his heart and no return of the gall bladder trouble.

CASE 12.—This as well as the next one illustrates the disastrous effect of gall-bladder disease on a heart already damaged by a valvular lesion, but for the sake of brevity will be given only in outline.

Patient.—In 1905 I was required to treat a man of 40 who had an unmistakable insufficiency of the aortic valve, probably of vascular origin. The complaint was more or less dyspnea and palpitation, but the man was always dwelling on his distress in his stomach. As the liver appeared greatly enlarged and sensitive to palpation the epigastric discomfort was thought due to hepatic congestion secondary to the cardiac disease.

Course of Disease.—At length, however, the man's gastric distress and inability to eat and digest food became so pronounced that I was led to examine the liver with particular care. To my surprise I at length was able to determine that the generally enlarged organ showed a contour and tenderness suggestive of a Riedel's lobe. On minute inquiry into the previous history it was ascertained that the man had suffered from symptoms highly suggestive of gallstone colic. A diagnosis of chronic cholecystitis was made and an operation advised, notwithstanding the serious state of the heart. The advice was heeded and an enormously enlarged and thickened gall bladder was opened and drained. It contained the usual tarry bile but no stones. The gastric symptoms were removed and the patient became able to eat, although the liver remained engorged and the heart inadequate. This latter condition better for a time, gradually grew worse and sudden death occurred some three months subsequent to the surgical procedure.

CASE 13.—*Patient.*—Mrs. F., Jewess, was in my care for about a year and a half suffering from dyspnea of effort due to mitral stenosis and occasional attacks of gallstone colic which latter she said she had for a number of years. During the fall of 1908 she was twice in a hospital.

Course of Disease.—During the first of these times the inadequacy for which she had been admitted was yielding satisfactorily to rest and the usual remedies when she was seized with one of her hepatic colics. Not only did the liver become greatly enlarged in the characteristic form of Riedel's lobe, but the heart dilated and became very rapid and arrhythmic,

while the patient herself grew so hysterical and despondent as to be controlled with difficulty. As the gall bladder condition improved the associated cardiac and nervous symptoms gradually disappeared and the patient at length went to her home improved but still far from well. A few weeks subsequently she was again sent to a hospital where she went through a repetition of her former experience, but in an aggravated degree. The liver became much enlarged and underneath its lower margin could be felt a soft, exquisitely sensitive body believed to be the distended gall bladder. Her heart weakness became alarming. Tricuspid insufficiency developed, the legs became edematous, the woman was unable to take food, vomiting was frequent and her nervousness was almost uncontrollable.

A digitalis preparation was administered intravenously; morphin and codein and cathartics were prescribed freely without appreciable benefit. The condition became so grave that both the patient and her husband were told that without an operation, which under existing circumstances would be attended with considerable risk, a restoration of compensation was impossible. Thereupon the patient decided to go home and place herself under the care of a competent neighboring physician. This she did and I was informed subsequently by the attending physician that at length, with subsidence of the gall-bladder symptoms, the heart regained a fair degree of competence, so that the woman was able again to get about. His treatment had consisted essentially of that employed in the hospital, digitalis intravenously administered, etc. It is believed that the history in this case justifies the opinion that with permanent removal of the gall-bladder complication, the heart would have regained and retained its compensation, but without an operation will go to pieces again so soon as another gallstone colic is experienced.

The contemplation of the foregoing cases raises the queries as to what the explanation is of the effect of gall-bladder disease on the heart and why not all persons with chronic cholecystitis develop cardiac symptoms. I acknowledge frankly my inability to answer these questions, but with regard to the second I suggest that a previous state of the myocardium may be a determining factor. A healthy heart muscle may endure such a disturbing influence or may recover quickly from its derangement of function. A myocardium already the seat of structural disease, on the contrary, is seriously affected by conditions of strain or by illness which otherwise would prove harmless. Therefore, since chronic infection of the gall bladder manifests itself chiefly in persons at or past middle age, when presumably the heart muscle is no longer so able to resist attacks, there are furnished the conditions capable of producing the symptom-complex reported in these cases.

The explanation of the baneful effects on the heart of some cases of gall-bladder disease and not of others is hypothetical, and accordingly several theories may be advanced: (1) the circulation in the blood of bacteria or their toxins; (2) the depressing influence of bile constituents on the myocardium; (3) disturbance of the splanchnic circulation and secondarily of the systemic circulation and heart; (4) a reflex inhibition through irritation of the vagus. It is quite possible that a different explanation is applicable to different cases and, moreover, that there must be a predisposing cause residing in the heart muscle, that is, chronic myocarditis, in consequence of which the heart is unfavorably affected by influences which a healthy myocardium would be able to resist.

1. As regards the first explanation: The disastrous—even fatal—effects on the heart of acute cholecystitis, of which every practitioner of experience must have seen instances, is a direct result of the acute infection which is capable of setting up a parenchymatous myocarditis.

In the same manner, but, of course, very slowly, a chronic gall-bladder infection may induce a chronic myocarditis. This view seems borne out by the necropsy findings in a case which I have briefly mentioned elsewhere. A woman of 33, who had suffered for nine years with cholelithiasis, died as a result of an operation on her gall bladder. The autopsy disclosed pronounced coronary sclerosis and an extreme degree of brown atrophy of the heart. Careful search failed to reveal signs of syphilis or any source of infection than that for which the woman had been subjected to surgical interference.

2. The depressing effect of cholemia on the heart has long been known clinically and demonstrated experimentally. Its most common manifestation is in a bradycardia, but the investigations of Stewart and King, of which a summary has been graciously furnished me, prove a toxic action on the myocardium of the pigment biliverdin and a blood-raising power of the bile salts. Furthermore, the combination of biliverdin with an alkaline metal, sodium or calcium in gallstones, prevents its entrance into the circulation and, therefore, its toxic action on the heart. These facts explain the pernicious effects of chronic cholecystitis whenever there is mild but prolonged cholemia shown by slight icterus. Not only may there be chronic, though slight, toxic effect on the heart, but the increase of blood pressure caused by the bile salts may be a factor in gradually overcoming the functional integrity of an already degenerated heart muscle. Given on top of this an acute exacerbation of the chronic cholecystitis and we have all the factors necessary to acute myocardial incompetence.

3. The third hypothesis of irritation of the splanchnic is one which should not be ignored, but in the present state of our knowledge can only be hinted at vaguely. Nevertheless, since the splanchnics are the regulators of the circulation, it may be that disturbance of the intra-abdominal circulation may prove an added factor by unfavorably affecting an already weakened heart and to lead to its dilatation and incompetence.

4. Lastly, the disastrous effect on the heart of biliary colic is probably a reflex result of stimulation of the filaments of the pneumogastric distributed to the wall of the gall bladder. This is more likely, since the formation of gallstones tends to protect the heart from the toxic effect of biliverdin by preventing its absorption into the blood. It is likely also that reflex derangement of the heart is occasioned when soreness is present and not intense pain. It does not seem applicable, however, to cases in which the gall-bladder symptoms are indigestion and not colic, although it must be acknowledged that in many of these cases palpation of the liver reveals marked tenderness. In chronic cholecystitis, therefore, without colic or subjective distress, the harmful effect on the heart must be ascribed to the circulation in the blood of biliverdin and possibly of bacterial toxins, to which may be added the prolonged blood-raising influence of the bile salts. Then if to these be conjoined the disturbing effects of chronic indigestion, we have a variety of factors capable of setting up the cardiac disorders observed. That more or less structural damage to the myocardium ensues seems likely from the readiness with which arrhythmia returns on slight disturbing conditions as in Cases 9 and 10.

The question of operative interference in cases of the kind here reported is one that must be met and answered by the physician according to the exigencies of

each case. That the cholecystitis should be recognized and drainage of the gall bladder instituted before cardiac symptoms arise is self-evident, and the cases are here reported in the hope that general practitioners may be impressed with the frequency of inconspicuous gall-bladder disease and probably may derive some aid in its recognition. Experience has convinced me that the opening and drainage of the gall bladder is attended with less danger, when properly performed, even though myocardial incompetence be present, than is non-interference. Did time permit, cases could be cited which would prove the peril to the patient and the culpability of the physician in leaving a chronically diseased gall bladder unoperated on when timely surgical intervention would have preserved the heart from irreparable damage and even spared life.

LITERATURE

A search of the literature, so far as that has been possible, with a view to discovering cases of the kind here reported, has not been very fruitful of results. Scattered references to the effects on the heart of acute and chronic cholecystitis and to the behavior of the heart during an attack of biliary colic exist in works devoted to the practice of medicine, but, with exception of a paper by Riesman and of certain cases therein cited, no report of the kind here made has been found. For example, Osler,¹ in describing the symptoms of biliary colic, says: "Palpitation and distress about the heart may be present, and occasionally a mitral murmur develops during the paroxysm, but the cardiac conditions described by some writers as coming on acutely in biliary colic are possibly pre-existent in these patients." Krehl,² also in an article on myocardial diseases, says what may be translated as follows:

Disorders of the liver, especially gallstones, and also diseases of the genital organs, occasion at times motor or sensory disturbances on the part of the heart; palpitation, slowing or acceleration of its rate, precordial pressure, pain or anxiety, at times indeed stenocardiac attacks. Often these symptoms are united with heavy and difficult breathing.

And Sticker,³ in his chapter on asthma, narrates a case of a woman whom he was called to treat for an asthmatic seizure that came on during an attack of gallstone colic and in whom the right heart was much dilated, both the asthma and dilatation disappearing after cessation of the pain. Doubtless similar passages might be found in other works.

In 1907 David Riesman⁴ published a report of two cases seen by him which displayed a systolic murmur at the apex and increased cardiac dulness during or directly following a gallstone colic. He also cites the following cases gathered from the literature: Gangolphe,⁵ 9 cases, 4 of cholelithiasis, 2 of emotional jaundice, 2 of hepatic cancer and 1 of cholangitis, in which cardiac murmurs occurred; Fabre,⁶ 8 cases of jaundice, the heart affected in 5; Rendu,⁷ in 1883, a case of hepatic colic in which systolic murmur developed, another case of colic and icterus in which there was marked arrhythmia.

mia, and another of catarrhal jaundice with gallop rhythm but no arrhythmia. Rendu also cites a case of Potain, which showed all the signs of tricuspid insufficiency without the recognized causes of that condition. According to Riesman, Tessier⁸ classifies the cardiac disturbances due to gastrohepatic diseases as (1) intensification of the second sound, (2) doubling of the second sound, (3) a tricuspid murmur, and (4) complete tricuspid incompetence with venous pulse. Other writers who have dealt with the development of cardiac murmurs in cases of jaundice are Revillout¹⁰ and Guéneau de Mussy, who, according to Revillout, was the first author to mention their occurrence. Quincke,¹¹ likewise mentioned by Riesman, recognizes a systolic murmur and intensification of the pulmonary second tone in icterus, but thinks them no more frequent than in other states attended with anemia.

In addition to the foregoing, I have discovered reports of cases of inflammatory lesions of the heart due to gall-bladder disease. Thus, Leva,¹² from Eichhorst's clinic at Zürich, reported two cases of ulcerative endocarditis resulting from disease of the gall bladder. The first was that of a 50-year-old multipara, who, after having suffered from icterus and gallstones, suddenly developed signs of endocarditis, from which she died in a short time. The autopsy showed gallstones in the common duct, expansion of the biliary passages and fresh thrombotic endocarditis of the tricuspid valve. The second case, in 1889, was that of a 44-year-old woman who was brought moribund to the hospital and died three days later. At the necropsy were discovered a fresh endocarditis developed on an old mitral disease, gallstones with dilation of the bile passages, abscess of the pancreas and meningitis. Leva cannot prove a definite connection between the disease of the gall bladder and the endocarditis, but any other etiologic factor for the valvulitis is wanting, and hence he concludes that in the first case the organism must have wandered from the gall bladder into the blood without leaving any changes behind, while in the second the pancreatic abscess and meningitis were undoubtedly secondary to the gall-bladder disease.

Leva failed to find similar cases in the German literature, but in the French found the following: Martineau¹³ in 1866, Netter and Martha¹⁴ in 1886—a case of multiple abscesses with gall gravel scattered along the intrahepatic bile ducts of the right lobe of the liver and an ulcerative endocarditis of the mitral valve. They believed that the two conditions were of common origin, since they identified the same organism in both situations and in the duodenum. These authors also cite reports by M. Luys (1864), Murchinson (1868), Jaecoud (1872), Roudot (1883) and Malibran (1884), but think the etiologic connection was not proven.

In 1893 C. Oddo¹⁵ of Marseilles reported a case of a 40-year-old man who, having had gallstone colic for several years, suddenly developed a typical attack of biliary colic and jaundice; two days later a feeble arrhythmic pulse with signs of pericarditis from which he died a few days later. Oddo did not find similar cases in literature.

L. Bard¹⁶ reported two cases of catarrhal icterus with bradycardia. In the first the pulse rate varied in the recumbent position between 48 and 52, but in the upright posture 84 to 88. In the recumbent position two jugular pulsations were seen to each cardiac systole and there was a doubling of the second sound, the third element being feeble and distant. In the second patient, the pulse in the dorsal decubitus was from 48 to 52, but in the erect posture 96. The heart sounds were the same as in the former case, but in the jugulars four pulsations were observed to each systole of the ventricles. The condition of the heart continued for several days after disappearance of the icterus.

Finally, the literature contains numerous references to the effect on the heart of the injection of bile into circulation, but, as these experiments are foreign to the class of cases here reported, they are omitted.

MANAGEMENT OF HEMORRHAGE FROM THE PARTURIENT CANAL*

JOHN F. MORAN, M.D.

WASHINGTON, D. C.

The successful management of hemorrhages of the parturient canal requires an intimate knowledge of their causes, unerring judgment, and immediate action for their prevention or control. It is important, therefore, to have in mind a well-developed plan of aggressive action in these emergencies; for on promptness and directness depend the safety of the mother and child.

These hemorrhages may occur before, during, or after labor. Those occurring before and during labor are either accidental or unavoidable. The accidental are due to the partial separation of the placenta from its normal situation in the upper segment of the uterus on account of some pathologic state of the uteroplacental union or traumatism. The hemorrhage may be concealed, visible, or both. The concealed may be dependent on bleeding between the uterine wall and the placenta, the margin of the latter remaining attached; to extravasation of the blood between the membranes and the wall of the uterus; to rupture into the amniotic sac; to stenosis of the cervix or its occlusion by the presenting part.

The unavoidable variety is due to the separation of a vicious implantation of the placenta in the lower segment of the uterus. It is designated lateral, marginal, or central prævia, according to its relative position to the cervix.

Hemorrhage occurring after the delivery of the fetus may originate in any part of the parturient canal; but postpartum hemorrhage proper is only from the placental site. It is primary when it occurs within twenty-four hours after birth of the child; it is secondary when it takes place at any time during the puerperium subsequent to the first twenty-four hours. While the true form is from the placental site, yet there are other cases in which the bleeding may originate from the cervix, vagina, or pelvic floor. Finally, one or more of these types may be combined.

FREQUENCY

Premature separation of the normally implanted placenta is not of common occurrence, and, in fact, its

very existence, though affirmed by some of the earlier obstetricians, was denied by others. Altogether, not over 400 cases of this type have been reported in the literature of the subject. These figures, however, do not give an approximate idea of its frequency, as, no doubt, many cases are not recognized, and others are credited to the præval variety. According to Holmes, it occurs about half as frequently as placenta prævia, or once in 500 labors.

Placenta prævia occurs, according to different writers, from once in 300 to once in 1,000 pregnancies. In 5,000 births at Columbia Hospital, there were sixteen cases of prævia, or one in 312.5 births.

Postpartum hemorrhage occurs in about 5 per cent. of all cases, and terminates fatally about once in 5,000 cases.

ETIOLOGY

The etiology of accidental and unavoidable hemorrhage is not definitely understood. The causes to which these abnormalities have been attributed are so numerous as to justify the inference that the real cause is unknown. As more than 70 per cent. of the cases occur in women who have borne children and the liability increases with each succeeding birth, multiparity and endometritis may be regarded as predisposing factors. The frequent association of nephritis with accidental hemorrhage is also of some significance. A short cord and traumatism may be direct factors in the production of hemorrhage from a normal placental site, while uterine myomata, malformation of the uterus and low implantation of the Fallopian tubes will help to explain some of the cases of prævia. Hofmeier explains the origin of the latter as the result of the fusion of the inferior pole of the reflexa with the decidua vera, while Strassman attributes it to defective vascularization of the decidua due to atrophic or inflammatory changes, making it necessary for the placenta to spread over a greater area in order to obtain its requisite supply of nutriment. The unusual size of the placenta in these cases, when we consider the development of the normal placenta as described by Peters, lends support to the latter theory.

While the pathologic factors of postpartum hemorrhage are not clearly understood, we know that anything that lowers the vitality of the system predisposes to atony of the uterus, and this would undoubtedly retard the contraction and retraction of its muscular fibers and thus favor hemorrhage.

Therefore, hemorrhagic diathesis, anemia, leucocythemia, nephritis and endometritis are regarded as predisposing causes. Cardiac, pulmonary or hepatic disease, producing obstruction or sluggishness of the maternal circulation, increases the liability to hemorrhage. Multiparity, precipitate labor, hydramnios and twin pregnancy, also favor postpartum hemorrhage. By far the most frequent cause of hemorrhage after birth is improper management of the expulsive and placental stages of labor. Hasty delivery, either by forceps, breech extraction, or version, may leave the organ unprepared for normal action. On the other hand, precipitate labor or protracted labor, by inducing inertia, may be attended by a similar result. The prolonged use of anesthetics, premature expulsion of the placenta, or a distended bladder, are likewise factors. Secondary hemorrhage is most frequently due to adherent placental tissue or the retention of blood clots.

TREATMENT

Unfortunately, owing to the paucity of our knowledge of the etiology of accidental and unavoidable hemorrhages, we are practically helpless to prevent them. Not so, however, with postpartum hemorrhage; for with proper management during pregnancy and labor, we can usually prevent it; and when it does occur, by the prompt use of measures at our command, we can, with almost absolute certainty, control it.

The management of hemorrhage from the normal placental site will depend on the amount of blood lost. When it is slight, rest in bed and the administration of sedatives, as in threatened abortion, may suffice. If the bleeding continues and the signs of collapse are pressing, the uterus should be emptied slowly or speedily, as the case demands. The cervix, according to the exigency, should be dilated either manually or with rubber bags, severed by multiple incisions, or vaginal Cesarean section performed, and the infant extracted with forceps or by version. After delivery, the uterus should be vigorously massaged to promote its contraction. If the placenta is not promptly expelled, it should be removed manually, the uterine cavity irrigated and packed with gauze to guard against postpartum hemorrhage. At the same time ergot should be given hypodermically further to insure uterine contraction. The vaginal tampon, which is so effectual in the treatment of prævia, has no place in the management of accidental hemorrhage, because of the danger of concealed hemorrhage. I have had two cases of accidental hemorrhage; both mothers recovered, but the infants perished before delivery.

In marginal and lateral prævia, rupture of the membranes permits the presenting part to descend and control the bleeding by compressing the placenta, and the labor, as a rule, terminates naturally. In this connection, however, the possibility of concealed hemorrhage must be borne in mind. Some years ago I had under my care a case of marginal prævia in a young multipara who had given birth to a number of children in rapid succession. The membranes ruptured spontaneously early in labor and there was a slight bleeding. Pains were tardy and feeble. Several hours after the onset of labor, signs of impending collapse were observed, and concealed hemorrhage was suspected. Examination showed the cervix dilated about two inches, but soft and yielding. Forceps were applied *in utero* and a living child delivered. Immediately following the extraction, more than a quart of dark clots were expressed from the uterus, which continued to relax, necessitating artificial expression of the placenta. Profuse hemorrhage followed, which was controlled by intrauterine irrigation and ergot hypodermically.

The tampon is a very valuable adjuvant in the treatment of prævia, in that it controls the hemorrhage, promotes softening and dilatation of the cervix, and at the same time enables the attendant to deliberately prepare, if need be, for immediate extraction.

Bipolar version, perforation, or separation of the placenta by the finger from its uterine attachment and afterward bringing down a foot, are the usual methods employed in central prævia. Bipolar version has reduced the maternal mortality of prævia, but as the child is used as a plug to control the hemorrhage its life is usually sacrificed. It was quite natural, then, that other measures would be evolved with the hope of reducing the high infant mortality while not decreasing the chances of the mother. Hence, abdominal Cesarean

section for placenta prævia has been advocated and performed from time to time for nearly twenty years. In my judgment, it has a limited but clearly defined field. It is particularly applicable in complete prævia in primiparæ with undilated cervix, and the results compare favorably with other methods of intervention. In 1905 I reviewed the literature of the subject and collected reports of 24 patients operated on by twenty-one operators. Seventeen of the cases were of the complete implantation, 2 lateral, and in 5 the variety was not mentioned. Fourteen patients were operated on according to the Sanger method, 7 by the Porro, and in 3 cases the methods were not stated. The majority of the patients were in unfavorable condition from repeated hemorrhages and were operated on after other methods had failed. Of the mothers who died, 3 succumbed to shock within twenty-four hours, 1 on the fourth day after secondary operation for obstruction of the bowels, and the fifth of septic peritonitis fifty-six hours after operation. Nineteen mothers and 11 infants recovered, a mortality of 20.8 per cent. and 54.3 per cent., respectively. Eight of the infants were either removed before viability or were dead before extraction, and 5 died from various causes in from several hours to four days after delivery. It is reasonable to suppose that the 5 who died after birth would have experienced the same fate after delivery *per vias naturales*, or might have perished after delivery, though certainly their chances of life were increased by the operation. These statistics are yet too small to formulate any fixed rule for guidance regarding the absolute and relative indications of Cesarean section for placenta prævia; these can be determined only by future experience.

Miller¹ has treated 14 cases of the central variety by preliminary ligation of the uterine arteries. His technic is to ligate the uterine artery on each side through the vagina, and then, having controlled the hemorrhage, he proceeds slowly to deliver. Two of his patients were so profoundly anemic, when first seen, that they died a few hours later, but the other 12 made good recoveries. In only 4 of the 14 cases was there any evidence of fetal life: in 3 of these the children were born alive, but all died prematurely within forty-eight hours. Miller asserts that the operation is simple, performed in some cases without anesthesia, does not decrease the possibility of future child-bearing, controls hemorrhage, allows the operator to proceed slowly and carefully to dilate the cervix and empty the uterus. He also states that the ligation prevents postpartum hemorrhage. He states that, while the fetal mortality may be slightly increased, there should be no maternal mortality except from infection. The method is ingenious and is an effective one in the treatment of placenta prævia, but, as in the older methods, the rights of the child are ignored. I have treated 7 cases of placenta prævia, 2 occurring in the same patient. One of the mothers died. Three of these cases were of the central variety, in which all of the infants were dead before the cases came under observation.

Many of the predisposing causes of postpartum hemorrhage can be overcome, and others at least mitigated, if treated during pregnancy. Some, however, can not be removed, and these may give much concern during the second and third stages of labor. The anemias, toxemias and leucocythemia are particularly prone to cause obstinate postpartum hemorrhage.

Whether to delay a rapid labor or to facilitate delivery in a protracted case in order to avert subsequent hemorrhage, is often difficult to decide.

Unquestionably, the most frequent cause of postpartum hemorrhage is the improper management of the third stage of labor, through neglect, or want of knowledge of the principle of contraction and retraction of the uterine muscular fibers which act as Nature's ligatures in controlling the uterine vessels, favor the formation of thrombi in the uterine sinuses, separate and extrude the placenta. Disregard of this important function of the uterine musculature is liable to be attended by grave consequences.

Every student and nurse should be taught at the bedside the method of grasping the fundus of the uterus, as proposed by Credé, for placental expression. No attempt should be made to deliver the placenta until the fundus rises to the level of the umbilicus, indicating that it has become detached from the uterine wall. At least a half-hour should elapse before expressing the placenta, unless there is actual uterine relaxation or hemorrhage. This allows the uterus to rest and prepare itself for the completion of the third stage. When the placenta is adherent, or if there is retention of clots, the fundus should be grasped in the palm of the hand, with the fingers on the posterior and the thumb on the anterior, and at the height of a contraction pressure made in the axis of the pelvis. If this fails to expel the placenta or clots, it may be necessary to introduce the hand into the uterus to remove them. But care must be exercised not to puncture the wall. In an emergency, bimanual compression, with one hand in the vagina pressing the cervix upward and grasping the fundus and forcing it downward against the symphysis, will effectually check the hemorrhage and allow time for preparing the intrauterine douche and subsequent tamponade. The placenta is sometimes retained and inverted, particularly if traction has been made on the cord. If it can not be expelled by uterine compression, the index-finger should be passed above the inverted edge, hooked into the placenta, and then slight traction will be sufficient to remove it.

I have not infrequently had to deal with postpartum hemorrhage of greater or less severity, and several of the cases are worthy of mention. The first occurred in a multipara who was attended by a midwife. I was summoned about two hours after delivery and found the patient in collapse. Examination showed the fundus uteri to be at the level of the umbilicus, and the uterus contained about a quart of clots. The débris was removed manually and further hemorrhage prevented by intrauterine irrigation and ergot hypodermically. The second case, that of a multipara, was also under the care of a midwife. When I reached the bedside, the patient had been delivered and was having a severe hemorrhage. Examination revealed a partially adherent placenta which was quickly peeled off with the finger and removed, and the uterus douched and packed. The third occurred in a case of Cesarean section complicated with inertia. After the extraction of the child, the uterus collapsed like an empty bag, and there was a marked hemorrhage. For a time it was thought that the Porro operation would be necessary to control the loss of blood. But the liberal use of salt solution, together with compression and gauze packing, finally checked the bleeding. All these patients required stimulants and hypodermoclysis to counteract shock; but recovered after protracted convalescence.

1. Miller, Harold A.: *Am. Jour. Obst.*, 1908, lviii, 1047.

In secondary postpartum hemorrhage, like the primary, preventive treatment is the most satisfactory. If the third stage and the puerperium are properly managed, this complication can usually be avoided. The direct treatment consists in completely removing placental debris or clots and securing complete uterine contraction.

One of the most alarming cases of secondary hemorrhage with which I have ever had to contend was in connection with a case of blighted ovum. When I reached the patient, she was blanched and almost pulseless. Free stimulation and hypodermoclysis were given and the uterus packed. The patient's critical condition made it necessary to defer the removal of the mole until the following day. The acute anemia yielded slowly to the treatment and the patient had to be sent to the seaside to promote recovery.

Injuries to the cervix, vagina and pelvic floor may be greatly minimized by careful attention to the mechanism of labor, retarding the passage of the child in rapid labors and avoiding undue haste in instrumental and operative deliveries. Hemorrhage from laceration of the cervix should be controlled, preferably by suture, and all tears of the vagina and pelvic floor, no matter how slight, should be closed immediately to guard against subsequent hemorrhage or infection.

After the control of the hemorrhage, anemia and shock will demand careful attention. Heat, stimulants, opiates, salt solution, administered intravenously, hypodermically or by rectum, should be employed according to the requirements of the particular case. Strychnin and ergot are of signal value in uterine hemorrhage; the former for its stimulating effect, and the latter on account of its specific action on the uterus, in reinforcing its contraction and thus insuring more complete occlusion of the uterine vessels.

In conclusion, owing to the want of knowledge of the cause of accidental and unavoidable hemorrhages, the mortality from such sources, even in the hands of the skilled and experienced obstetrician, is high. Postpartum hemorrhage and lacerations of the parturient canal, on the other hand, are among the most amenable of obstetrical complications, but require an intimate acquaintance with the proper procedure under such conditions. My reason, therefore, for bringing to attention a subject so familiar to all is not its frequency, but the emergency of the situation which demands early recognition, prompt decision and action, in that it involves the life of the mother and the child, and as regards the physician himself, his professional reputation.

2426 Pennsylvania Avenue, N.-W.

The Relation of Necrosis of Fatty Tissues and Arteriosclerosis to Diabetes Mellitus.—L. Bleibtren (*Arch. f. ges. Physiol.*, cxxiv, 52), in connection with his work on diabetes, observed a case of advanced diabetes mellitus in a man aged 39, associated with extensive fat necrosis in the region of the pancreas, in the mesentery, in the costal and diaphragmatic pleura and especially in the duodenal serosa. There were no necrotic changes in the tissues of the pancreas itself. In accord with Pflüger's observations, Bleibtren advocates as a tenable hypothesis that the extensive fat necrosis around the pancreas and duodenum had materially damaged or destroyed the nervous connections of these organs, producing as a consequence diabetes mellitus. Similarly in a case of diabetes with associated extensive arteriosclerosis in the pancreatic and abdominal arteries, Bleibtren sees extensive disturbance of the visceral nerves with resulting diabetes.

PAIN AND POTT'S DISEASE, WITH ESPECIAL REFERENCE TO BACKACHE*

C. C. WHOLEY, M.D.
PITTSBURG

The term "backache" is one which is frequently employed, and often very loosely. By "backache" the laity mean any "misery" or discomfort, located anywhere between the foramen magnum and the gluteal folds. As most backaches are situated below the diaphragm, however, this part of the anatomy is usually meant when backache is spoken of outside the profession. While backache is at times a valuable symptom, the indefiniteness which is so often associated with it makes it misleading to both the public and the physician. The large number of kidney-cures (many of which contain as much as 40 per cent. alcohol), which are so conspicuously advertised, tells plainly to what mischief it may lead. Many a benighted individual, by mistaking the ache over the upper sacral region, very common in neurasthenia or fatigue, for an indication of Bright's, doubtless often induces an incipient nephritis in kidneys which were normal before the exhibition of the "cure" from which he has sought relief. I believe that the number of backaches dependent on lesions of the kidneys is considerably less than we have in the past been disposed to think. A case I will cite shows that the physician also may misinterpret the significance of backache, and illustrates the great need of caution in diagnosing the significance of pain symptoms generally.

First Attack.—On July 28, 1908, I found A. H., a tall, lean Afro-American, in his thirty-sixth year, suffering with excruciating pains in his left hypochondriac and left lumbar regions. The thighs were flexed on the abdomen and the patient was doubled up on his left side between hot bricks and hot-water bottles, wearing a facies indicative of acute pain and distress. The pulse was regular, full and tense, temperature normal. The attack had come on suddenly, with some nausea at the onset. The pain radiated to the left lumbar region and left groin. The abdomen muscles were rigid over the painful area and there was tenderness on pressure, particularly over the region of the kidney both in front and behind. There was no history of painful or blood-colored urine. The only previous history of any moment was that, following an attack of what had been called grip, the patient had for a year been below his previous standard good health. The patient gave an indefinite account of attacks of pain similar to the present, experienced during childhood.

Course of Disease and Subsequent History.—Two ½ gr. doses of morphin given hypodermically brought relief and the attack subsided. An examination of the urine revealed a clear amber fluid of 1015 specific gravity, showing a small trace of albumin and a few white corpuscles. Blood examination showed no increase in the leucocytes. Tenderness over the left kidney continued after the attack and the organ felt enlarged to the palpating hand. The urine was freely voided after the attack of colicky pain. A provisional diagnosis of renal or ureteral calculus was made.

Two weeks later an attack came on precisely similar in character to the one just described, but there was no abatement of the pain, except under large doses of morphin, until six days later, when an exploratory operation was performed by Dr. Acheson Stewart at the Mercy Hospital. A thorough examination of the kidney, its pelvis and ureter, failed to discover stone or other pathologic condition than a moderately enlarged organ with a shallow-fissured surface. Radiography had previously shown no shadow of a foreign body, but we had assumed that, if present, its texture was of such nature that a shadow could not be observed. A very slight leucocytosis was present before the operation. There followed a speedy con-

* Read before the College of Physicians, Pittsburg, April 22, 1909.

valescence from the operation, with cessation of pain crises for two months. At the end of this time some weakness of the back was still complained of and the urine showed a few leucocytes and doubtful red cells. Ten weeks after the operation and again at twelve weeks attacks recurred like the one first described. A course of salicylates was now followed by relief from pain for two months but more or less invalidism persisted. Then there set in a continuous, very severe pain in the muscles of the back in the lumbar region and toward the right hip joint behind. This resisted all efforts at successful treatment—antirheumatic, antisiphilitic, antineuritic and antineurasthenic—when, after a month the pain centered entirely in the right hypochondriac and right lumbar regions. The patient was again placed in the hospital, where, on suspicion and a history of an ancient penial sore, large doses of potassium iodid were prescribed. Under three days of this medication the pain shifted to the right thigh, knee and right leg (the anterior border of the tibia)—these areas claiming first one and then another, the location of greatest severity from day to day. An important difference was now noticed for the first time in the temperature chart; a previously normal temperature began showing an evening rise of about one degree. We believed that a tuberculous focus had been stirred into activity by the potassium iodid and were about to attempt a verification of this by a von Pirquet test when, with a rather sudden focusing of the pain to the right of the lumbar vertebrae and the appearance of a bulging, tender mass at this point, our interesting and varied trail of diagnosis was brought to an abrupt close. The exploring needle established the already unmistakable diagnosis of a tuberculous abscess, the process having undoubtedly existed for a long time and given rise to the varied manifestations of pain already described.

Janeway has called attention to persistent lumbago as a symptom of importance in masked Pott's disease; this was truly conspicuous in my own case. The radiating pains and painful areas alluded to may have arisen from compression involvement, through inflammatory exudates on the roots of the spinal nerves, as they emerged from between the vertebrae. The pain locations and steady progression from above downward leads one to think this probable. A colleague has since related to me an experience almost identical with the above. In an adult farmer, after six months, a mass presented in the right lumbar region. In neither his case nor my own was any spinal deformity noticeable. Tenderness over some of the spinal vertebrae had been noticed by me, but its significance misinterpreted. Spinal pain following jarring movements or twisting of the spinal column (symptoms of Pott's disease) were disregarded until the diagnosis was already apparent.

I have given the above case in some detail because of its valuable suggestions in the study of pain symptoms, and because I am convinced that the above experience is not an uncommon one in such obscure cases of spinal caries. The symptom of pain was throughout the most conspicuous feature. While a valuable symptom when rightly interpreted, pain in this instance repeatedly diverted our attention from important signs which would have given an earlier diagnosis. The case was especially characterized by backache, this giving rise to three mistaken diagnoses: calculus, rheumatism and neurasthenia. Backache is an incident in so many affections that a few words regarding it seem appropriate at this time. Taken alone it is generally of little value. Indeed, it may prove a positive hindrance. In the lumbar region especially we must think of fatigue pain from overexertion, anemia and neurasthenia. The backache of flatulence and loaded colon must be thought of, particularly in women. In kidney lesions the value of backache has been overstated in nephritis, as it is probably of significance only in the acute processes; in other

forms of kidney pathology—floating kidney, lithemic, perinephritic and tumor conditions, though present at times, it plays no positive part in diagnosis. Backaches which are symmetrically placed are, of course, of far less diagnostic significance than those which are unilateral. Schmidt, in his valuable treatise on pain, calls attention to this, as also to the tenderness on pressure found on the right side in appendicitis with retrocecal abscess, hepatalgia and cholelithiasis; on the left side in gastric ulcer, perisplenitis and pancreatic lesions. "The demonstration of the alimentary modification of backache is of importance, since it occurs in ulcerative processes of the stomach or large intestine. In these as well as in disorders of the colon, for example, carcinoma, the pain often occurs within even a few minutes after the ingestion of cold fluids or solid food." Chronic prostatitis is apt to be overlooked as a cause of backache. W. C. Bryant, in a recent paper,¹ emphasizes this fact, and offers an explanation, in the light of Henry Head's brilliant researches, in the intimate relationship existing between the pudic nerve, from which the prostate receives its spinal fibers, with the roots of the sacral and lumbar plexuses. This prostatically caused backache leads to diagnoses of sciatica and lumbago and at times simulates renal colic so closely that nephrotomy has been performed for stone.

While speaking of referred pains, it is well to remember that what is true of the prostate is true of the various internal organs. A well-known physiologist² tells us:
